ACKNOWLEDGEMENT OF GOVERNMENT SUPPORT

 This invention was made with Government support under Small Business Innovation Research Grant No. 1 R43 AI45724-01A2, awarded by the National Institute of
30 Allergy and Infectious Disease. The Government may have certain rights in this invention.

1.0 FIELD OF THE INVENTION

The present invention relates to molecules expressed in cells of the immune system. In particular, the invention relates to a transmembrane protein that contains certain classical cadherin characteristics.

2.0 BACKGROUND OF THE INVENTION

The generation of an immune response against an antigen is carried out by a number of distinct immune cell types that work in concert within the context of a particular antigen. The helper T cell (T_H) plays a pivotal role to coordinate two types of antigen-specific immune response; *i.e.*, cellular and humoral immune response. Recognition of antigen by T cells requires the formation of a specialized junction between the T cell and the antigen-presenting cell (APC) called the “immunological synapse” (Dustin, *et al.*, 1998, Cell 94: 667-677). The immune synapse orchestrates recruitment and exclusion of specific proteins from the contact area by an unknown mechanism and is thought to be initiated by T-cell antigen receptor (TCR) recognition of peptides bound to MHC molecules (antigen) (Monk, *et al.* 1998, Nature 395: 82). However, the low affinity of the TCR for antigen as well as limited number of ligands makes it unlikely that TCR: antigen interaction alone is sufficient to drive the formation of the immunological synapse (Matsui *et al.*, 1994, Proc. Natl. Acad. Sci. U.S.A. 91: 12861-12866).

Costimulatory molecules such as CD4, ICAM-1, LFA-1, CD28, CD2 have been proposed to stabilize the cell-cell contact (Dustin, *et al.*, 1999, Science 283: 649). However, since these molecules are recruited to the synapse after activation they cannot account for the high specificity and avidity during the early phases of T-cell antigen recognition. Recent work demonstrated that a portion of the T cell surface at the leading edge is specialized to mediate the early phases of synapse formation (Negulescu, *et al.*, 1996, Immunity 4: 421-430). Such a specialization must be a pre-formed structure containing cell surface adhesion proteins (ectodomains) to augment TCR engagement and corresponding cytoplasmic portions (endodomains) to transduce signals and bind cytoskeleton to maintain structural/functional polarity.

The ectodomain of the pre-formed synapse or “immune gateway” was recently discovered and is created in part by CLASP-1 (U.S.S.N. 09/411,328, filed October 1, 1999; PCT/US99/22996). In addition to cadherin motifs, CLASP-1 also contains a CRK-SH3 binding domain, tyrosine phosphorylation sites, and coiled/coil domains suggesting direct

interaction with cytoskeleton and regulation by adaptor molecules such as CRK. The *CLASP-1* transcript is present in lymphoid organs and neural tissue, and the protein is expressed by T and B lymphocytes and macrophages in the MOMA-1 subregion of the marginal zone of the spleen, an area known to be important in T: B cell interaction. CLASP-1 staining of individual T and B cells exhibits a preactivation structural polarity, being organized as a “ball” or “cap” structure in B cells, and forming a “ring”, “ball” or “cap” structure in T cells. The placement of these structures is adjacent to the microtubule-organizing center (“MTOC”). CLASP-1 antibody staining indicates that CLASP-1 is at the interface of T-B cell conjugates that are fully committed to differentiation. Antibodies to the extracellular domain of CLASP-1 also block T-B cell conjugate formation and T cell activation.

3.0 SUMMARY OF THE INVENTION

The present invention relates to a cell surface molecule, a member of a new multigene family designated cadherin-like asymmetry protein(s) (“CLASP(s)”). In particular, it relates to a polynucleotides comprising a coding sequences for CLASPs, polynucleotides that selectively hybridize to the complement of a CLASP coding sequence, expression vectors containing such polynucleotides, genetically-engineered host cells containing such polynucleotides, CLASP polypeptides, CLASP fusion proteins, therapeutic compositions, CLASP domain mutants, antibodies specific for CLASP polypeptides, methods for detecting the expression of CLASP, and methods of inhibiting an immune response by interfering with CLASP function. A wide variety of uses are encompassed by the invention, including but not limited to, treatment of autoimmune diseases and hypersensitivities, prevention of transplantation rejection responses, and augmentation of immune responsiveness in immunodeficiency states.

The invention therefore relates to methods and compositions relating to CLASP polynucleotides and polypeptides (i.e., full length human or mouse CLASP 1-6 polynucleotides or polypeptides of fragments thereof.

In one aspect, the invention provides an isolated CLASP-2 polynucleotide that is: (a) a polynucleotide that has the sequence of SEQ ID NO: 1, 3, 5 or 9; (b) a polynucleotide that hybridizes under stringent hybridization conditions to (a) and encodes a polypeptide having the sequence of SEQ ID NO: 2, 4, 6 or 10 or an allelic variant or homologue of a polypeptide having the sequence of SEQ ID NO: 2, 4, 6 or 10; or (c) a polynucleotide that hybridizes under stringent hybridization conditions to (a) and encodes a polypeptide with at

least 25 contiguous residues of the polypeptide of SEQ ID NO: 2, 4, 6 or 10; or (d) a polynucleotide that hybridizes under stringent hybridization conditions to (a) and has at least 12 contiguous bases identical to or exactly complementary to SEQ ID NO: 1, 3, 5, or 9. In a related aspect, the invention provides a CLASP-2 polynucleotide wherein the polynucleotide
5 encodes a polypeptide that binds to the PDZ domain of PSD95, DLG1 or neDLG. In another related aspect, the invention provides a CLASP-2 polynucleotide wherein the polynucleotide encodes a polypeptide that has a binding affinity of at least 10^4 M^{-1} for binding PSD95, DLG1 or neDLG.

In one aspect, the invention provides a CLASP-2 polynucleotide that encodes
10 a polypeptide having the full-length sequence of SEQ ID NO: 2, 4, 6, or 10 or the cDNA sequence encoded by the inserts of ATCC Deposit Nos: PTA-1562, PTA-1563 and PTA-1573.

In another aspect, the invention provides a CLASP-2 polynucleotide that encodes a polypeptide having the full-length sequence of Isoform 1, Isoform 2, or Isoform 3
15 or the cDNA sequence encoded by the inserts of AVC-PD14 (ATCC Deposit No. PTA-2611) and AVC-PD19 (ATCC Deposit No. PTA-2614).

In another aspect, the invention further provides an isolated CLASP-2 polynucleotide comprising a nucleotide sequence that has at least 90% percent identity to SEQ ID NO: 1, 3, 5 or 9 as calculated using FASTA wherein said sequences are aligned so
20 that highest order match between said sequences is obtained.

The invention further provides an isolated polypeptide comprising a nucleotide sequence that has at least 90% sequence identity to SEQ ID NO: 2, 4, 6 or 10 and is immunologically crossreactive with SEQ ID NO: 2, 4, 6 or 10 or shares a biological function with native CLASP-2.

25 The invention also provides vectors, such as expression vectors, comprising a polynucleotide sequence of the invention. In other embodiments, the invention provides host cells or progeny of the host cells comprising a vector of the invention. In certain embodiments, the host cell is a eukaryote. In other embodiments, the expression vector comprises a CLASP polynucleotide in which the nucleotide sequence of the polynucleotide is
30 operatively linked with a regulatory sequence that controls expression of the polynucleotide in a host cell. In certain embodiments, the invention provides a host cell comprising a CLASP polynucleotide, wherein the nucleotide sequence of the polynucleotide is operatively linked with a regulatory sequence that controls expression of the polynucleotide in a host cell, or progeny of the cell.

In another aspect, the invention further provides a CLASP-2 polynucleotide that is an antisense polynucleotide. In a preferred embodiment, the antisense polynucleotide is less than about 200 bases in length. In other embodiments, the invention provides an antisense oligonucleotide complementary to a messenger RNA comprising SEQ ID NO: 1, 3,
5 5 or 9 and encoding CLASP-2, wherein the oligonucleotide inhibits the expression of CLASP-2.

In another aspect, the invention provides an isolated DNA that encodes a CLASP-2 protein as shown in SEQ ID NO: 2, 4, 6 or 10. In certain embodiments, the CLASP-2 polynucleotide is RNA.

10 The invention provides a method for producing a polypeptide comprising: (a) culturing the host cell containing a CLASP-2 polynucleotide under conditions such that the polypeptide is expressed; and (b) recovering the polypeptide from the cultured host cell or its cultured medium.

The invention further provides an isolated CLASP-2 polypeptide encoded by a
15 CLASP-2 polynucleotide. In some embodiments, the CLASP-2 polypeptide has the amino acid sequence of SEQ ID NO: 2, 4, 6 or 10, or a fragment thereof. In some embodiments, the isolated CLASP-2 polypeptide is cell-membrane associated. In other embodiments, the isolated CLASP-2 polypeptide is soluble. In other embodiments, the soluble CLASP-2 polypeptide is fused with a heterologous polypeptide.

20 The invention further provides an isolated CLASP-2 protein having the sequence as shown in SEQ ID NO: 2, 4, 6 or 10. In some embodiments, the invention provides a CLASP-2 protein comprising the sequence as shown in SEQ. ID. NO: 1 and variants thereof that are at least 95% identical to SEQ ID. NO: 2 and specifically binds a cytoskeletal protein. In certain embodiments the cytoskeletal protein is spectrin.

25 The invention further provides an isolated antibody that specifically binds to a polypeptide having the amino acid sequence as shown in SEQ ID NO: 2, 4, 6 or 10, or a binding fragment thereof. In some embodiments the antibody is monoclonal. In other embodiments, the invention provides a hybridoma capable of secreting the antibody.

The invention further provides a method of identifying a compound or agent
30 that binds a CLASP-2 polypeptide comprising: i) contacting a CLASP-2 polypeptide with the compound or agent under conditions which allow binding of the compound to the CLASP-2 polypeptide to form a complex and ii) detecting the presence of the complex.

The invention further provides a method of detecting a CLASP-2 polypeptide in a sample, comprising: (a) contacting the sample with a CLASP-2 antibody or binding

fragment and (b) determining whether a complex has been formed between the antibody and with CLASP-2 polypeptide.

The invention further provides a method of detecting a CLASP-2 polypeptide in a sample, comprising: (a) contacting the sample with a CLASP-2 polynucleotide or a
5 polynucleotide that comprises a sequence of at least 12 nucleotides and is complementary to a contiguous sequence of the CLASP-2 polynucleotide and (b) determining whether a hybridization complex has been formed.

The invention further provides a method of detecting a CLASP-2 nucleotide in a sample, comprising: (a) using a polynucleotide that comprises a sequence of at least 12
10 nucleotides and is complementary to a contiguous sequence of a CLASP-2 polynucleotide in an amplification process; and (b) determining whether a specific amplification product has been formed.

The invention further provides pharmaceutical compositions comprising a CLASP-2 polynucleotide, a CLASP-2 polypeptide, or a CLASP-2 antibody and a
15 pharmaceutically acceptable carrier.

In one aspect, the invention provides a method of inhibiting an immune response in a cell comprising: (a) interfering with the expression of a CLASP-2 gene in the cell; (b) interfering with the ability of a CLASP-2 protein to mediate cell-cell interaction
(e.g., interfering with a heterotypic and/or homotypic interaction) between CLASP-2 and an
20 extracellular protein; (c) interfering with the ability of a CLASP-2 protein to bind to another protein. In some such methods, the cell is a T cell or a B cell. Some such methods comprise contacting the cell with an effective amount of a polypeptide which comprises the amino acid sequence of SEQ ID NO: 2, 4, 6 or 10 or a fragment thereof.

In another aspect, the invention provides a method of inhibiting an immune
25 response in a subject, comprising administering to the subject a therapeutically effective amount of an antibody which specifically binds a polypeptide having the sequence of SEQ ID NO: 2, 4, 6 or 10.

In another aspect, the invention provides a method of preventing or treating a CLASP-2-mediated disease comprising administering to a subject in need thereof a
30 therapeutically effective amount of a CLASP-2 pharmaceutical composition. In some such methods, the CLASP-2-mediated disease is an autoimmune disease.

The invention further provides a method of treating an autoimmune disease in a subject caused or exacerbated by increased activity of T_H1 cells consisting of administering a therapeutically effective amount of a CLASP-2 pharmaceutical composition to the subject.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1. Nucleotide and predicted amino acid sequence of CLASP-2A cDNA. Notable protein motifs are indicated above the nucleotide sequence in bold. Potential initiator methionines are underscored. The notable, predicted protein motifs are: a cadherin cleavage site encoded by nucleotides 854-868, a cadherin ectodomain (EC) encoded by nucleotides 1253-1264, a transmembrane domain encoded by nucleotides 2861-2917, a coiled coil domain encoded by nucleotides 3579-3682, a second coiled coil domain encoded by nucleotides 3827-3937, and a PDZ binding motif (PBM) encoded by nucleotides 4046-4057.

Figure 2. A. Schematic of CLASP-2 splice variants. Splice variants are compared to Human (h) CLASP-2A. Numbers above hCLASP-2A line diagram indicate where splice variations comprising deletions and insertions relative to hCLASP-2A are found. Abbreviations: "KIAA" KIAA1058 sequence (Genbank Accession No. AB028981). **B.** Nucleotide and predicted amino acid sequence of CLASP-2A cDNA. Notable protein motifs are indicated above the nucleotide sequence in bold. Exact position of insertions and deletions are indicated above the CLASP-2A sequence with arrows and "x", respectively. The nucleotide sequence of insertions schematized in FIG. 2A are indicated above the arrow. The insertions and deletions are as follows (numeration refers to Human CLASP-2A nucleotide sequence): Nucleotides 1966-2034 are deleted in CLASP-2D. Nucleotides 2219-2224 are deleted in CLASP-2B. There is an insertion of 69 amino acids at nucleotide 2927 found in CLASP-2D. The nucleotide sequence for this insertion is:
AAGCAGTCCAGTGGGAGCCGCCCTTCTCCCCACAGCCATAGCGCCTGCCTGAG
GAGGAGCCGGGGAG and encodes amino acids AVQWEPPLPHSHSACLRRSRG (one letter amino acid abbreviation). This amino acid sequence encodes a putative SH3 binding domain. There is another deletion at between nucleotides 3011-3079 found in CLASP-2E. CLASPs 2B, 2C, 2D and 2E contain an insertion at nucleotide 3153 with the nucleotide sequence of:
TGAGAGGCTGGCCCATCTGTATGACACGCTGCACCGGGCCTACAGCAAAGTGAC
CGAGGTCATGCACTCGGGCCGCAGGCTTCTGGGGACCTACTTCCGGGTAGCCTTC
TTCGGGCAGGCAGCGCAATACCAGTTTACAGACAGTGAAACAGATGTGGAGGGA
TT. The entire sequence is found in CLASP-2D and encodes amino acids
ERLAHLYDTLHRAYSKVTEVMHSGRLLGTYFRVAFFGQAAQYQFTDSETDVEG
while the underline sequence is found in CLASPs 2B, 2C, and 2E and encodes amino acids
ERLAHLYDTLHRAYSKVTEVMHSGRLLGTYFRVAFFGQG. This amino acid

sequence encodes a putative immunoreceptor tyrosine-based activation motif (ITAM). There is a two nucleotide deletion in Human CLASP-2C found at nucleotides 3586 and 3587. There is an insertion of 8 nucleotides found only in Human CLASP-2D with sequence: CTGGGATG at nucleotide 3937. This insertion puts a stop codon into the CLASP-2D
5 nucleotide sequence.

Figure 3. A. Alignment of nucleotide sequences of the CLASP-2 isoforms. Sequences were aligned using ClustalW **B.** Alignment of amino acid sequence of the CLASP-2 isoforms. Sequences were aligned using ClustalW. One letter amino acid abbreviation is used.

Figure 4. Expression of CLASP-2 in human cell lines and human tissues as determined by Northern hybridization. A CLASP-2-specific DNA fragment was generated by PCR from a CLASP-2 cDNA clone (HC2-5'), using primers HC2AS2 and HC2S1. The fragment was labeled by incorporation of radioactive ³²P dCTP. **A.** Expression in human tissues. The labeled DNA fragment was used as a probe on a human Multiple Tissue
10 Northern (Clontech MTN Blot, #7780-1). A single band is clearly detect migrating at approximately 7.5 kb in placenta, heart kidney and lung in the Multiple Tissue Northern. Slight expression is detected in liver, skeletal muscle and brain. **B.** Expression in hematopoietic cell lines. A Northern with RNA from multiple cells lines was hybridized with the same hCLASP-2 probe. A similarly migrating band is detected in Jurkat (T-cell derived),
15 9D10 (B-cell derived) and 293 (human kidney derived) cell lines. There are multiple weaker bands in the 9D10 lane indicating possible splice variants of hCLASP-2. Weak expression is also detected in the mouse cell lines CH27 (B cell lymphoma) and 3A9 (T-cell hybridoma). Since hybridization and washing were carried out at high stringency, this indicates that the human CLASP-2 probe may cross-react with mouse CLASP mRNA.

Figure 5. A. Amino acid sequence of human and rat CLASP proteins. Sequences were aligned using ClustalW. One letter amino acid abbreviation used. Protein motifs are found within the labeled boxes. A “-” indicates gaps that are placed to acquire a best overall alignment. Other abbreviations: “HC2A” Human CLASP-2 sequence, “KIAA” KIAA1058 sequence (Genbank Accession No. AB028981), “rat” TRG gene (Genbank
25 Accession No. X68101), “HC4” Human CLASP-4 sequence, “HC1” Human CLASP-1 sequence, “HC3” Human CLASP-3 sequence, “HC5” Human CLASP-5 sequence. **B.**

30

Alignment of DOCK motifs found within the human CLASPs and compared to canonical DOCK motifs. Consensus amino acids found within all DOCK motifs are also indicated.

Figure 6. A. Nucleotide and predicted amino acid sequence of CLASP-2A cDNA. Notable protein motifs are indicated (see FIG. 1 legend for details). Additionally, boundaries between exons and introns are indicated by arrows. These boundaries were defined by sequencing Bacterial Artificial Chromosomes (BACs) containing genomic DNA corresponding to CLASP-2. BACs were sequenced using primers derived from exon sequences corresponding to the CLASP-2 cDNA. Each exon/intron boundary is noted (as “Ref” with an appropriate reference number) above the cDNA sequence. The references contain exact nucleotide location of introns. The names and nucleotide numbers of the primers that were used in sequence reactions are also indicated. All nucleotide numbers refer to CLASP-2A cDNA sequence. As shown in the reference, not all of the sequence from sequencing reactions produced sequence matching the cDNA. These nucleotide sequences that did not match the exon sequence for CLASP-2 were considered to be intron sequences.

B. Alignment of human and rat CLASP amino acid sequences by ClustalW. Notable protein motifs are indicated (see FIG. 1 Legend for additional details). Additionally, the exon/intron borders described in part A are indicated with vertical lines between appropriate amino acids. Reference numbers are indicated in the right margin and correspond to references in Fig 6A and B.

Figure 7. Southern hybridization analysis of CLASP-2. Genomic DNA from HeLa cells or a BAC DNA clone was digested with EcoRI or HindIII (genomic DNA) or Pst I (BAC DNA) and electrophoresed and transferred to nylon membrane by standard methods. For a probe, a CLASP-2-specific DNA fragment was generated by PCR from a CLASP-2 cDNA clone (HC2-5'), using primers HC2AS2 and HC2S1. The fragment was labeled by incorporation of radioactive ³²P dCTP. Probe HC2.1 is 800 bp long and it recognizes two fragments (~4.5 kb and 1.85 kb) on Eco RI digested genomic DNA. Three fragments are revealed by this probe when hybridized to digested DNA of BACs 4 and 6, with the two major ones identical in size to those detected on genomic DNA.

Figure 8. Expression of human CLASP-1 (hCLASP-1) CLASP-1 and CLASP-2 Glutathion-S-Transferase (GST) fusion proteins. Nucleotides encoding a portion of the hCLASP-2A intracellular domain (nucleotides 3230-4065) were subcloned into pGEX vectors (Pharmacia). Recombinant plasmids were transformed into E. coli (strain DH5α),

and transformed strains were grown by standard conditions. While in log phase cells were either induced (I) with IPTG (0.1 mM final concentration) or left uninduced (U). After several additional hours of growth cells were harvested and soluble protein lysates generated by standard methods. Aliquots of the protein lysates were eletrophoresed on SDS-PAGE
 5 along with molecular mass standards. The gel was stained with Coomassie Blue and shows that fusion proteins migrated with their predicted molecular masses of 59 and 57 kD for hCLASP-1 and hCLASP-2, respectively.

Figure 9. A. Binding of CLASP-2 C-terminal 20 amino acids to PDZ domains. 20 μ M biotinylated synthetic peptide corresponding to the C-terminal 20 amino
 10 acids of CLASP-2 was reacted with the indicated plate bound GST fusion proteins (none = no GST fusion protein coated onto plate). Error bars indicate standard deviation of duplicate measurements. **B.** Affinity of CLASP 2 – PDZ interactions. Varying concentrations of biotinylated CLASP-2 peptide were reacted with plate bound GST alone, GST-DLG1, GST-NeDLG, and GST-PSD95 fusion proteins. The binding to GST alone (< 0.1 OD units) was
 15 subtracted from the binding to the fusion proteins and the remaining signal was divided by the signal observed upon addition of 30 μ M CLASP-2 peptide to each PDZ domain-containing protein (0.4 – 1.0 OD units) and plotted. The plotted data was fit to a saturation binding curve, yielding an apparent affinity of 7.5 μ M for NeDLG- CLASP-2 interaction, 21 μ M for DLG1- CLASP-2 interaction, and 45 μ M for PSD95-CLASP-2 interaction. Data are
 20 means of duplicate data points, with standard errors between duplicate data points < 10%. **C.** Inhibition of CLASP-2 – PDZ binding. 5 μ M biotinylated synthetic peptide corresponding to the C-terminal 20 amino acids of CLASP-2 was reacted with the indicated, plate-bound PDZ domain-containing GST fusion proteins in the presence or absence of 100 μ M competitor peptide. CLASP-2 Inhibitor refers to a synthetic peptide composed of the eight C-terminal
 25 amino acids of CLASP-2. KV1.3 Inhibitor refers to a synthetic peptide composed of the 19 C-terminal amino acids of KV1.3, a lymphocyte potassium channel. The amino acid sequence of the KV1.3 inhibitor is TTNNNPNSAVNIKKIFTDV. **D.** Inhibition of KV1.3 – PDZ binding. 5 μ M biotinylated synthetic peptide corresponding to the C-terminal 19 amino acids of KV1.3 was reacted with the indicated, plate-bound PDZ-domain containing GST
 30 fusion proteins in the presence or absence of 100 μ M CLASP-2 Inhibitor (see FIG. 9C legend).

Figure 10A-H. Preliminary nucleotide sequences of CLASP-2 cDNAs.

Figure 11. A) Full length cDNA sequence and predicted amino acid translation of the human CLASP-2 gene. Predicted initiator methionine starts at nucleotide +1. Three independent 1st exons (indicated as 11A, 11B and 11C) splice into the second exon starting at nucleotide -101. The sequence appearing in FIG. 1 corresponds to nucleotides 1884 through 6690 of FIG 11A. B) Differences between the human CLASP-2 cDNA isoforms. In addition to the differential first exon usage indicated in A, sequencing multiple, independent cDNA products revealed nucleotide polymorphisms (allelic variations) between CLASP-2 cDNA isoforms. Additionally, differential exon usage through alternative splicing events was discovered. The use of the exon in B leads to a premature stop codon that can generate a soluble form of CLASP-2. C. Schematic of human CLASP-2 cDNAs. The top line represents nucleotide numbering found in FIG. 11A. Line (i) represents CLASP-2 cDNA shown in FIG. 1 above; line (ii) represents the full length CLASP-2 isoforms, where there are three CLASP-2 full length cDNA isoforms (A + Z, B + Z, and C + Z). Each of the isoforms uses a unique first exon (A, B, and C) (*see* FIG. 11A) that splices into the rest of the cDNA from exon 2 onwards represented by Z. The portion of the cDNA represented by Z itself has alternative splice and nucleotide polymorphisms that are shown in FIG. 2 above. Line (iii) represents the additional 5' sequence with a small region of overlap between nucleotides 1884 to 2109 in FIG. 11A and nucleotides 1-225 of FIG. 1.

Figure 12. Sequence of human CLASP-2 exons and intron boundaries. A Sequence of human CLASP-2 exons and intron borders. Stretches of noncontiguous genomic sequence from the Human Genome Project (GENBANK entry gi9988160) were aligned using the human CLASP-2 cDNA as a template and Sequencher sequence analysis software (Gene Codes Corp). 22 exons representing approximately the 5' 20% of the human CLASP-2 cDNA sequence are presented in predicted 5' to 3' order. Exon sequences are underlined and are flanked by intron sequence. Nucleotide numbers in parentheses refer to the exon sequence within the uniquely-generated, contiguous gi9988160 sequence, which is located in B. B. Ordered stretch of human genomic DNA at the CLASP-2 locus aligned from noncontiguous, shotgun sequencing from the Human Genome Project using the human CLASP-2 sequence from FIG. 5A to determine genomic DNA fragment order and orientation.

Figure 13. Amino acid alignment and comparison between the human (h) CLASP family members. Amino acid sequences were aligned using ClustalW. The

alignment is presented in order of their greatest pairwise similarity scores. Single letter amino acid abbreviations are used. Astericks indicate complete identity, while colons and periods indicate sequence similarity among CLASP family members. Dashes indicate gaps inserted in the amino acid sequence to facilitate alignment. Labelled boxes are domains with similarity to known protein motifs; unlabelled boxes represent regions of similarity between all CLASPs and may represent CLASP-specific domains.

Figure 14. Expression of CLASP-2 upon T-cell activation as assayed by Northern analysis. Jurkat cells were activated using PMA, ionomycin, and α CD28. RNA was prepared from cell culture aliquots at 0, 1, 2, 4, 8, 14 hours post activation and Northern analysis was performed (A). Hybridization signals obtained with a CLASP-2-specific probe were quantified using a phosphor imager system. Relative signal intensities (refers to total signal of the specific probe used) are shown in the bar diagram (B). The ethidium staining of the Northern gel (A) demonstrates even RNA loading.

DETAILED DESCRIPTION

5.0 Definitions

Except when noted, the terms “patient” or “subject” are used interchangeably and refer to mammals such as human patients and non-human primates, as well as experimental animals such as rabbits, rats, and mice, and other animals.

The term “biological sample” as used herein is a sample of biological tissue, fluid, or cells that contains CLASPs or nucleic acid encoding CLASP proteins. Such samples include, but are not limited to, tissue isolated from humans. Biological samples may also include sections of tissues such as frozen sections taken for histologic purposes. A biological sample is typically obtained from a eukaryotic organism, preferably eukaryotes

such as fungi, plants, insects, protozoa, birds, fish, reptiles, and preferably a mammal such as rat, mice, cow, dog, guinea pig, or rabbit, and most preferably a primate such as chimpanzees or humans.

The term “treating” includes the administration of the compounds or agents of the present invention to prevent or delay the onset of the symptoms, complications, or biochemical indicia of a disease, alleviating the symptoms or arresting or inhibiting further development of the disease, condition, or disorder (*e.g.*, autoimmune disease). Treatment may be prophylactic (to prevent or delay the onset of the disease, or to prevent the manifestation of clinical or subclinical symptoms thereof) or therapeutic suppression or alleviation of symptoms after the manifestation of the disease.

The term “lymphocyte” as used herein has the normal meaning in the art, and refers to any of the mononuclear, nonphagocytic leukocytes, found in the blood, lymph, and lymphoid tissues, *i.e.*, B and T lymphocytes.

The terms “isolated,” or “purified,” refer to material that is substantially free from components that normally accompany it as found in its native state (*e.g.*, recombinantly produced or purified away from other cell components with which it is naturally associated). Purity and homogeneity are typically determined using analytical chemistry techniques such as polyacrylamide gel electrophoresis or high performance liquid chromatography. The term “purified” denotes that a nucleic acid or protein gives rise to essentially one band in an electrophoretic gel. Particularly, it means that the nucleic acid or protein is at least 85% pure, more preferably at least 95% pure, and most preferably at least 99% pure.

The terms “nucleic acid” and “polynucleotide” are used interchangeably and refer to refers to DNA, RNA and nucleic acid polymers containing known nucleotide analogs or modified backbone residues or linkages, which are synthetic, naturally occurring, and non-naturally occurring, which have similar binding properties as the reference nucleic acid, and which are metabolized in a manner similar to the reference nucleotides. Examples of such analogs include, without limitation, phosphorothioates, phosphoramidates, methyl phosphonates, chiral-methyl phosphonates, 2-O-methyl ribonucleotides, peptide-nucleic acids (PNAs).

The terms “polypeptide,” “peptide” and “protein” are used interchangeably herein to refer to a polymer of amino acid residues. The amino acids may be natural amino acids, or include an artificial chemical mimetic of a corresponding naturally occurring amino acid.

As used herein a “nucleic acid probe” is defined as a nucleic acid capable of specifically binding to a target nucleic acid of complementary sequence (*e.g.*, through complementary base pairing). As used herein, a probe may include natural (*i.e.*, A, G, C, or T) or modified bases (7-deazaguanosine, inosine, and the like). In addition, the bases in a probe may be joined by a linkage other than a phosphodiester bond, so long as it does not interfere with hybridization (*e.g.*, probes may be peptide nucleic acids). The probes can be directly labeled as with isotopes, chromophores, lumiphores, chromogens, or indirectly labeled such as with biotin to which a streptavidin complex may later bind.

The term “recombinant” when used with reference, *e.g.*, to a cell, or nucleic acid, protein, or vector, indicates that the cell, nucleic acid, protein or vector, has been modified by the introduction of a heterologous nucleic acid or protein or the alteration of a native nucleic acid or protein, or, in the case of cells, to progeny of a cell so modified. Thus, for example, recombinant cells express genes that are not found within the native (non-recombinant) form of the cell or express native genes that are otherwise abnormally expressed, under expressed or not expressed at all.

The term “heterologous” when used with reference to portions of a nucleic acid indicates that the nucleic acid comprises two or more subsequences that are not found in the same relationship to each other in nature. For instance, the nucleic acid is typically recombinantly produced, having two or more sequences from unrelated genes arranged to make a new functional nucleic acid, *e.g.*, a promoter from one source and a coding region from another source. Similarly, a heterologous protein indicates that the protein comprises two or more subsequences that are not found in the same relationship to each other in nature (*e.g.*, a fusion protein).

The term “sequence identity” refers to a measure of similarity between amino acid or nucleotide sequences, and can be measured using methods known in the art, such as those described below:

The terms “identical” or percent “identity,” in the context of two or more nucleic acids or polypeptide sequences, refer to two or more sequences or subsequences that are the same or have a specified percentage of amino acid residues or nucleotides that are the same (*i.e.*, 60% identity, preferably 65%, 70%, 75%, 80%, 85%, 90%, or 95% identity over a specified region (see, *e.g.*, SEQ ID NO: 1), when compared and aligned for maximum correspondence over a comparison window, or designated region as measured using one of the following sequence comparison algorithms or by manual alignment and visual inspection.

The phrase “substantially identical,” in the context of two nucleic acids or polypeptides, refers to two or more sequences or subsequences that have at least of at least 60%, often at least 70%, preferably at least 80%, most preferably at least 90% or at least 95% nucleotide or amino acid residue identity, when compared and aligned for maximum
5 correspondence, as measured using one of the following sequence comparison algorithms or by visual inspection. Preferably, the substantial identity exists over a region of the sequences that is at least about 50 bases or residues in length, more preferably over a region of at least about 100 bases or residues, and most preferably the sequences are substantially identical over at least about 150 bases or residues. In a most preferred embodiment, the sequences are
10 substantially identical over the entire length of the coding regions.

The phrase “sequence similarity” in the context of two nucleic acids or polypeptides, refers to two or more sequences that are identical or in the case of amino acids, have homologous amino acid substitutions at either 50%, often at least 60%, often at least 70%, preferably at least 80%, most preferably at least 90% or at least 95% of the
15 indicated positions.

For sequence comparison, typically one sequence acts as a reference sequence, to which test sequences are compared. When using a sequence comparison algorithm, test and reference sequences are entered into a computer, subsequence coordinates are designated, if necessary, and sequence algorithm program parameters are designated. Default program
20 parameters can be used, or alternative parameters can be designated. The sequence comparison algorithm then calculates the percent sequence identities for the test sequences relative to the reference sequence, based on the program parameters. For sequence comparison of nucleic acids and proteins to CLASP nucleic acids and proteins, the BLAST and BLAST 2.0 algorithms and the default parameters discussed below are used.

25 A “comparison window”, as used herein, includes reference to a segment of any one of the number of contiguous positions selected from the group consisting of from 20 to 600, usually about 50 to about 200, more usually about 100 to about 150 in which a sequence may be compared to a reference sequence of the same number of contiguous positions after the two sequences are optimally aligned. Methods of alignment of sequences
30 for comparison are well-known in the art. Optimal alignment of sequences for comparison can be conducted, *e.g.*, by the local homology algorithm of Smith & Waterman, 1981, Adv. Appl. Math. 2: 482), by the homology alignment algorithm of Needleman & Wunsch, 1970, J. Mol. Biol. 48: 443, by the search for similarity method of Pearson & Lipman, 1988, Proc. Natl. Acad. Sci. U.S.A. 85: 2444, by computerized implementations of these algorithms

(FASTDB (Intelligenetics), BLAST (National Center for Biomedical Information), GAP, BESTFIT, FASTA, and TFASTA in the Wisconsin Genetics Software Package, Genetics Computer Group, 575 Science Dr., Madison, WI), or by manual alignment and visual inspection (see, *e.g.*, Ausubel *et al.*, 1987 (1999 Suppl.), Current Protocols in Molecular Biology, Greene Publishing Associates and Wiley Interscience, N.Y.)

A preferred example of an algorithm that is suitable for determining percent sequence identity and sequence similarity is the FASTA algorithm, which is described in Pearson, W.R. & Lipman, D.J., 1988, Proc. Natl. Acad. Sci. U.S.A. 85: 2444. See also W. R. Pearson, 1996, Methods Enzymol. 266: 227-258. Preferred parameters used in a FASTA alignment of DNA sequences to calculate percent identity are optimized, BL50 Matrix 15: -5, k-tuple= 2; joining penalty= 40, optimization= 28; gap penalty -12, gap length penalty =-2; and width= 16.

Another preferred example of algorithm that is suitable for determining percent sequence identity and sequence similarity are the BLAST and BLAST 2.0 algorithms, which are described in Altschul *et al.*, 1977, Nuc. Acids Res. 25: 3389-3402 and Altschul *et al.*, 1990, J. Mol. Biol. 215: 403-410, respectively. BLAST and BLAST 2.0 are used, with the parameters described herein, to determine percent sequence identity for the nucleic acids and proteins of the invention. Software for performing BLAST analyses is publicly available through the National Center for Biotechnology Information (<http://www.ncbi.nlm.nih.gov/>). This algorithm involves first identifying high scoring sequence pairs (HSPs) by identifying short words of length W in the query sequence, which either match or satisfy some positive-valued threshold score T when aligned with a word of the same length in a database sequence. T is referred to as the neighborhood word score threshold (Altschul *et al.*, *supra*). These initial neighborhood word hits act as seeds for initiating searches to find longer HSPs containing them. The word hits are extended in both directions along each sequence for as far as the cumulative alignment score can be increased. Cumulative scores are calculated using, for nucleotide sequences, the parameters M (reward score for a pair of matching residues; always > 0) and N (penalty score for mismatching residues; always < 0). For amino acid sequences, a scoring matrix is used to calculate the cumulative score. Extension of the word hits in each direction are halted when: the cumulative alignment score falls off by the quantity X from its maximum achieved value; the cumulative score goes to zero or below, due to the accumulation of one or more negative-scoring residue alignments; or the end of either sequence is reached. The BLAST algorithm parameters W, T, and X determine the sensitivity and speed of the alignment. The BLASTN program (for nucleotide sequences)

uses as defaults a wordlength (W) of 11, an expectation (E) of 10, M=5, N=-4 and a comparison of both strands. For amino acid sequences, the BLASTP program uses as defaults a wordlength of 3, and expectation (E) of 10, and the BLOSUM62 scoring matrix (see Henikoff & Henikoff, 1989, Proc. Natl. Acad. Sci. U.S.A. 89: 10915) alignments (B) of
5 50, expectation (E) of 10, M=5, N=-4, and a comparison of both strands.

The BLAST algorithm also performs a statistical analysis of the similarity between two sequences (see, *e.g.*, Karlin & Altschul, 1993, Proc. Natl. Acad. Sci. U.S.A. 90: 5873-5787). One measure of similarity provided by the BLAST algorithm is the smallest sum probability (P(N)), which provides an indication of the probability by which a match between
10 two nucleotide or amino acid sequences would occur by chance. For example, a nucleic acid is considered similar to a reference sequence if the smallest sum probability in a comparison of the test nucleic acid to the reference nucleic acid is less than about 0.2, more preferably less than about 0.01, and most preferably less than about 0.001.

Another example of a useful algorithm is PILEUP. PILEUP creates a multiple
15 sequence alignment from a group of related sequences using progressive, pairwise alignments to show relationship and percent sequence identity. It also plots a tree or dendrogram showing the clustering relationships used to create the alignment. PILEUP uses a simplification of the progressive alignment method of Feng & Doolittle, 1987, J. Mol. Evol. 35: 351-360. The method used is similar to the method described by Higgins & Sharp, 1989, CABIOS 5: 151-
20 153. The program can align up to 300 sequences, each of a maximum length of 5,000 nucleotides or amino acids. The multiple alignment procedure begins with the pairwise alignment of the two most similar sequences, producing a cluster of two aligned sequences. This cluster is then aligned to the next most related sequence or cluster of aligned sequences. Two clusters of sequences are aligned by a simple extension of the pairwise alignment of two
25 individual sequences. The final alignment is achieved by a series of progressive, pairwise alignments. The program is run by designating specific sequences and their amino acid or nucleotide coordinates for regions of sequence comparison and by designating the program parameters. Using PILEUP, a reference sequence is compared to other test sequences to determine the percent sequence identity relationship using the following parameters: default
30 gap weight (3.00), default gap length weight (0.10), and weighted end gaps. PILEUP can be obtained from the GCG sequence analysis software package, *e.g.*, version 7.0 (Devereaux *et al.*, 1984, Nuc. Acids Res. 12: 387-395).

Another preferred example of an algorithm that is suitable for multiple DNA and amino acid sequence alignments is the CLUSTALW program (Thompson, J. D. *et al.*,

1994, Nucl. Acids. Res. 22: 4673-4680). ClustalW performs multiple pairwise comparisons between groups of sequences and assembles them into a multiple alignment based on homology. Gap open and Gap extension penalties were 10 and 0.05 respectively. For amino acid alignments, the BLOSUM algorithm can be used as a protein weight matrix (Henikoff
5 and Henikoff, 1992, Proc. Natl. Acad. Sci. U.S.A. 89: 10915-10919).

A “label” is a composition detectable by spectroscopic, photochemical, biochemical, immunochemical, or chemical means. For example, useful labels include ³²P, fluorescent dyes, electron-dense reagents, enzymes (*e.g.*, as commonly used in an ELISA), biotin, digoxigenin, or haptens and proteins for which antisera or monoclonal antibodies are
10 available (*e.g.*, the polypeptide of SEQ ID NO: 1 can be made detectable, *e.g.*, by incorporating a radiolabel into the peptide, and used to detect antibodies specifically reactive with the peptide).

The term “sorting” in the context of cells as used herein to refers to both physical sorting of the cells, as can be accomplished using, *e.g.*, a fluorescence activated cell
15 sorter, as well as to analysis of cells based on expression of cell surface markers, *e.g.*, FACS analysis in the absence of sorting.

The phrase “selectively (or specifically) hybridizes to” refers to the binding, duplexing, or hybridizing of a molecule only to a particular nucleotide sequence under stringent hybridization conditions when that sequence is present in a complex mixture (*e.g.*,
20 total cellular or library DNA or RNA).

The phrase “specifically (or selectively) binds” to an antibody refers to a binding reaction that is determinative of the presence of the protein in a heterogeneous population of proteins and other biologics. Thus, under designated immunoassay conditions, the specified antibodies bind to a particular protein at least two times the background and do
25 not substantially bind in a significant amount to other proteins present in the sample.

The phrase “specifically bind(s)” or “bind(s) specifically” when referring to a peptide refers to a peptide molecule which has intermediate or high binding affinity, exclusively or predominately, to a target molecule. The phrases “specifically binds to” refers to a binding reaction which is determinative of the presence of a target protein in the presence
30 of a heterogeneous population of proteins and other biologics. Thus, under designated assay conditions, the specified binding moieties bind preferentially to a particular target protein and do not bind in a significant amount to other components present in a test sample. Specific binding to a target protein under such conditions may require a binding moiety that is selected for its specificity for a particular target antigen. A variety of assay formats may be

used to select ligands that are specifically reactive with a particular protein. For example, solid-phase ELISA immunoassays, immunoprecipitation, Biacore and Western blot are used to identify peptides that specifically react with PDZ domain-containing proteins. Typically a specific or selective reaction will be at least twice background signal or noise and more
5 typically more than 10 times background. Specific binding between a monovalent peptide and a PDZ-containing protein means a binding affinity of at least 10^4 M^{-1} , and preferably 10^5 or 10^6 M^{-1} .

The phrase “homotypic interaction” refers to the binding of a given protein to another molecule of the same protein (*e.g.*, the binding of hCLASP-2 to hCLASP-2). The
10 phrase “heterotypic interaction” refers to the binding of a given protein to a different protein or other molecule (*e.g.*, the binding of hCLASP to a PDZ domain-containing protein or the binding of a transcription factor to DNA).

The phrase “immune cell response” refers to the response of immune system cells to external or internal stimuli (*e.g.*, antigen, cytokines, chemokines, and other cells)
15 producing biochemical changes in the immune cells that result in immune cell migration, killing of target cells, phagocytosis, production of antibodies, other soluble effectors of the immune response, and the like.

The terms “B lymphocyte response” and “B lymphocyte activity” are used interchangeably to refer to the component of immune response carried out by B lymphocytes
20 (*i.e.* the proliferation and maturation of B lymphocytes, the binding of antigen to cell surface immunoglobulin, the internalization of antigen and presentation of that antigen via MHC molecules to T lymphocytes, and the synthesis and secretion of antibodies).

The terms “T lymphocyte response” and “T lymphocyte activity” are used here interchangeably to refer to the component of immune response dependent on T
25 lymphocytes (*i.e.*, the proliferation and/or differentiation of T lymphocytes into helper, cytotoxic killer, or suppressor T lymphocytes, the provision of signals by helper T lymphocytes to B lymphocytes that cause or prevent antibody production, the killing of specific target cells by cytotoxic T lymphocytes, and the release of soluble factors such as cytokines that modulate the function of other immune cells).

30 The term “immune response” refers to the concerted action of lymphocytes, antigen presenting cells, phagocytic cells, granulocytes, and soluble macromolecules produced by the above cells or the liver (including antibodies, cytokines, and complement) that results in selective damage to, destruction of, or elimination from the human body of

invading pathogens, cells or tissues infected with pathogens, cancerous cells, or, in cases of autoimmunity or pathological inflammation, normal human cells or tissues.

Components of an immune response may be detected *in vitro* by various methods that are well known to those of ordinary skill in the art. For example, (1) cytotoxic
5 T lymphocytes can be incubated with radioactively labeled target cells and the lysis of these target cells detected by the release of radioactivity, (2) helper T lymphocytes can be incubated with antigens and antigen presenting cells and the synthesis and secretion of cytokines measured by standard methods (Windhagen A; *et al.*, 1995, Immunity 2(4): 373-80), (3) antigen presenting cells can be incubated with whole protein antigen and the
10 presentation of that antigen on MHC detected by either T lymphocyte activation assays or biophysical methods (Harding *et al.*, 1989, Proc. Natl. Acad. Sci., 86: 4230-4), (4) mast cells can be incubated with reagents that cross-link their Fc-epsilon receptors and histamine release measured by enzyme immunoassay (Siraganian, *et al.*, 1983, TIPS 4: 432-437).

Similarly, products of an immune response in either a model organism (*e.g.*,
15 mouse) or a human patient can also be detected by various methods that are well known to those of ordinary skill in the art. For example, (1) the production of antibodies in response to vaccination can be readily detected by standard methods currently used in clinical laboratories, *e.g.*, an ELISA; (2) the migration of immune cells to sites of inflammation can be detected by scratching the surface of skin and placing a sterile container to capture the
20 migrating cells over scratch site (Peters *et al.*, 1988, Blood 72: 1310-5); (3) the proliferation of peripheral blood mononuclear cells in response to mitogens or mixed lymphocyte reaction can be measured using ³H-thymidine; (4) the phagocytic capacity of granulocytes, macrophages, and other phagocytes in PBMCs can be measured by placing PMBCs in wells together with labeled particles (Peters *et al.*, 1988); and (5) the differentiation of immune
25 system cells can be measured by labeling PBMCs with antibodies to CD molecules such as CD4 and CD8 and measuring the fraction of the PBMCs expressing these markers.

As used herein, the phrase “signal transduction pathway” or “signal transduction event” refers to at least one biochemical reaction, but more commonly a series of biochemical reactions, which result from interaction of a cell with a stimulatory compound
30 or agent. Thus, the interaction of a stimulatory compound with a cell generates a “signal” that is transmitted through the signal transduction pathway, ultimately resulting in a cellular response, *e.g.*, an immune response described above.

A signal transduction pathway refers to the biochemical relationship between a variety of signal transduction molecules that play a role in the transmission of a signal from

one portion of a cell to another portion of a cell. Signal transduction molecules of the present invention include, for example, CLASP proteins. As used herein, the phrase “cell surface receptor” includes molecules and complexes of molecules capable of receiving a signal and the transmission of such a signal across the plasma membrane of a cell. An example of a “cell surface receptor” of the present invention is the T cell receptor (TCR). As used herein, the phrase “intracellular signal transduction molecule” includes those molecules or complexes of molecules involved in transmitting a signal from the plasma membrane of a cell through the cytoplasm of the cell, and in some instances, into the cell’s nucleus. In the present invention, CLASPs can be referred to as “intracellular signal transduction molecules”, but can also be referred to as “signal transduction molecules”.

A signal transduction pathway in a cell can be initiated by interaction of a cell with a stimulator that is inside or outside of the cell. If an exterior (*i.e.*, outside of the cell) stimulator (*e.g.*, an MHC-antigen complex on an antigen presenting cell) interacts with a cell surface receptor (*e.g.*, a T cell receptor), a signal transduction pathway can transmit a signal across the cell’s membrane, through the cytoplasm of the cell, and in some instances into the nucleus. If an interior (*e.g.*, inside the cell) stimulator interacts with an intracellular signal transduction molecule, a signal transduction pathway can result in transmission of a signal through the cell’s cytoplasm, and in some instances into the cell’s nucleus.

Signal transduction can occur through, *e.g.*, the phosphorylation of a molecule; non-covalent allosteric interactions; complexing of molecules; the conformational change of a molecule; calcium release; inositol phosphate production; proteolytic cleavage; regulation or exchange of nucleotide mono-, di- or tri- phosphates, cyclic nucleotide production and diacylglyceride production. Typically, signal transduction occurs through phosphorylating a signal transduction molecule. According to the present invention, a CLASP signal transduction pathway refers generally to a pathway in which a CLASP protein regulates a pathway that includes engaged-receptors, kinases, PKC-substrates, G proteins, and other molecules.

5.1. Introduction

The present invention relates to novel transmembrane proteins, termed CLASPs. CLASP family members contain an endodomain that displays the appropriate properties to organize the cytoskeleton and interact with signal transduction apparatus of the immune gateway and signaling pathways.

CLASPs function in cells of the immune system, *e.g.*, T cells and B cells, as well as non-immune cells. The CLASP proteins function in a variety of cellular processes, particularly related to immune function, regulation of T cell and B cell interactions, T cell activation, other cellular activation, and in the organization, establishment and maintenance
5 of the “immunological synapse” (see Dustin *et al.*, 1999, Science 283: 680-682; Paul *et al.*, 1994, Cell 76: 241-251; Dustin *et al.*, 1996, J. Immunol. 157: 2014; Dustin *et al.*, 1998, Cell 94: 667), including signal transduction, cytoskeletal interactions, and membrane organization.

Without intending to be bound by a particular mechanism or limited in any way, the CLASP proteins are believed to be a component of the lymphocyte organelle called
10 the “immune gateway” that creates a docking site for cell-cell contact during antigen-presentation. It is believed the cytoplasmic domains of CLASP proteins organize it into a patch at the leading edge of T cells. The carboxy-terminus encoded sequences of some CLASPs may mediate interaction with PDZ domain proteins and with cytoskeletal proteins (*e.g.*, spectrin or ankyrin) to connect CLASPs to the microtubule network and hold receptors
15 or other signaling molecules at a polarized configuration just above the microtubule-organizing center (“MTOC”). Thus, when T cells engages a B cell acting as an APC, the CLASP molecules are organized at the interface of the two cells.

Modulating the expression of the CLASP protein, and interference with, or enhancement of, CLASP protein interactions with other proteins has a number of beneficial
20 physiological effects, *e.g.*, altered signaling in response to antigen, altered T and B cell response to antigen, and modulation of T cell activation. Disorders that can be treated by disrupting CLASP function, include without limitation, multiple sclerosis, juvenile diabetes, rheumatoid arthritis, pemphigus, pemphigoid, epidermolysis bullosa acqvista, lupus, endometriosis, toxemia or pregnancy induced hypertension, pruritic urticarial papules and
25 plaques of pregnancy (PUPPP), herpes gestationis, impetigo herpetiformis, pruritus gravidarum, placenta-related disorders, and Rh incompatibility.

In another aspect, the present invention provides methods and reagents for detection of CLASP expression and CLASP-expressing cells. Abnormal expression patterns or expression levels are diagnostic for immune and other disorders. For example, diseases
30 characterized by overproduction or depletion of lymphocytes in blood or other organs may be detected or monitored by monitoring the level of CLASP polypeptide or mRNA in a biological sample (*e.g.*, peripheral blood), *e.g.*, the number or percentage of CLASP expressing cells. Diseases characterized by overproduction of T cells include, *e.g.*, leukemia (both ALL and CLL), lymphoma (including non-Hodgkins lymphoma, Burkitt’s lymphoma,

mycosis fungoides, and sezary syndrome), EBV, CMV, toxoplasmosis, syphilis, typhoid, brucellosis, tuberculosis, influenza, hepatitis, serum sickness, and thyrotoxicosis. Diseases associated with the depletion of T cells include, *e.g.*, HIV and myelodysplasia. Diseases associated with the overproduction of B cells include, *e.g.*, leukemia (both ALL and CLL),
5 non-Hodgkins lymphoma, Burkitt's lymphoma, myeloma, EBV, CMV, toxoplasmosis, syphilis, typhoid, brucellosis, tuberculosis, influenza, hepatitis, serum sickness, and thyrotoxicosis. Diseases associated with the depletion of B cells include, *e.g.*, myelodysplasia.

In many embodiments described herein, "CLASP-2" is provided solely to
10 provided an example of a CLASP. Any other CLASP molecule, *e.g.*, CLASP-1, -3, -4, -5, -6, from humans or mice may be used in the subject methods, or replace CLASP-2 in the subject compositions.

For Example, if CLASP-2 polynucleotide, polypeptides or antibody thereto is recited herein in a composition, then that CLASP-2 polynucleotide, polypeptides or antibody
15 thereto may be replaced by an equivalent CLASP-1, CLASP-3, or CLASP-4, CLASP-5, or CLASP-6 polynucleotide, polypeptides or antibody thereto or any mouse CLASP polynucleotide, polypeptides or antibody thereto.

Also, if CLASP-2 polynucleotide, polypeptides or antibody thereto is recited herein in a method, then that CLASP-2 polynucleotide, polypeptides or antibody thereto may
20 be replaced by an equivalent CLASP-1, CLASP-3, or CLASP-4, CLASP-5, or CLASP-6 polynucleotide, polypeptides or antibody thereto or any mouse CLASP polynucleotide, polypeptides or antibody thereto.

Further, if "CLASP" is recited herein, any CLASP, *e.g.*, CLASP-1, CLASP-2, CLASP-3, or CLASP-4, CLASP-5, or CLASP-6, from either human or mouse, is referred to.
25 In certain embodiments, "CLASP" refers to the human CLASP-2.

5.2. CLASP cDNA and Polypeptide Structure

The cDNA and polypeptide sequences of human and mouse CLASPs is described in the sequence listing and figures.

The CLASP-2 protein is characterized by multiple forms produced by
30 alternative exon usage (*i.e.*, production of splice variants). In one naturally occurring form, CLASP-2 has the structure shown in FIG. 1. However, as discussed in detail *infra*, the CLASP-2 gene encodes a variety of gene product due to alternative splicing of mRNA. FIG.

2 shows the nucleotide sequence and conceptual translation of human CLASP-2 polypeptides:

hCLASP-2A cDNA (SEQ ID NO: 1) and hCLASP-2A polypeptide (SEQ ID NO: 2).
5 hCLASP-2B cDNA (SEQ ID NO: 3) and hCLASP-2B polypeptide (SEQ ID NO: 4).
hCLASP-2C cDNA (SEQ ID NO: 5) and hCLASP-2C polypeptide (SEQ ID NO: 6).
hCLASP-2D cDNA (SEQ ID NO: 7) and hCLASP-2D polypeptide (SEQ ID NO: 8).
10 hCLASP-2E cDNA (SEQ ID NO: 9) and hCLASP-2E polypeptide (SEQ ID NO: 10).

Unless specifically referred to, the phrase “human CLASP-2 (hCLASP-2)” is used herein refers to hCLASP-2A, hCLASP-2B, hCLASP-2C and hCLASP-2E. “hCLASP-2D” cDNA is also known as KIAA1058, which was described by Kikuno *et al.*, 1999, *DNA Res.* 6, 197-205 as a cDNA from brain encoding a protein of unknown function.

CLASP polypeptides typically include a leader sequence, followed in certain cases by a PH domain that may localize it to the cell membrane, and a long domain that may contain phosphorylation sites, PDZ binding sites, guanine nucleotide binding functions, and coiled-coiled regions. The present invention provides a polynucleotide having the sequence of SEQ. ID. NO: 1, or a fragment thereof, and a polypeptide having the sequence of SEQ. ID NO: 2, or a fragment thereof. In addition, the invention provides polynucleotides comprising CLASP genomic sequences, CLASP homologues from other species, naturally occurring alleles of hCLASPs, and hCLASP variants as described herein, and methods for using CLASP polynucleotides, polypeptides, antibodies and other reagents.

5.2.1. CLASP Polypeptide Domains

As is shown in FIG. 1, one naturally occurring CLASP-2 cDNA encodes a polypeptide characterized by several structural and functional domains and defined sequence motifs. To provide guidance to the practitioner, the structural features are described *infra*.
30 However, it will be understood that the present invention is not limited to polypeptides that include all, or any particular one of these domains or motifs. For example, a CLASP-2 fusion protein of the invention contains only the putative extracellular domain of CLASP-2. Similarly, the CLASP-2A polypeptide of SEQ ID NO: 2 does not have the ITAM motifs (discussed *infra*) found in the CLASP-2B and 2C polypeptides.

It will be appreciated that the structurally (and functionally) different domains of CLASP-2 polypeptides (and the corresponding region of the mRNA) are of interest, in part, because they may be separately targeted or modified (*e.g.*, deleted or mutated) to affect the activity or expression of a CLASP-2 gene product (in order to, for example, modulate an immune response). For example, the putative extracellular domain of a CLASP-2 protein can be targeted (*e.g.*, using an anti-CLASP monoclonal antibody to (a) block the interaction of a CLASP-2-expressing cell (*e.g.*, a T cell) and a second cell (*e.g.*, a B cell) displaying a protein that is bound by CLASP-2 (*i.e.*, a CLASP-2 ligand). Similarly, an intracellular domain (*e.g.*, ITAM or DOCK, see *infra*) can be targeted to interfere with signal transduction without interfering with extracellular ligand binding.

Generally, inhibiting CLASP expression or CLASP polypeptide function will result in modulation of immune function including, for example, changing the threshold for T cell activation by affecting formation of the immune synapse. Modulation of immune function can be screened and quantitated by a number of assays known in the art and described herein (see also §5.14).

5.2.1.1. Signal Peptide

The human CLASP-2 sequence presented in FIG. 1 encodes two potential start sites for translation. The first predicted methionine appears at nucleotide 278 (ATG). The second methionine appears at nucleotide 476. Both have an acceptable consensus sequence for a translational start (A/GxxATGG; Kozak, M., 1996, *Mamm. Genome* 7(8): 563-74). A polypeptide beginning at the second methionine is also predicted to encode a signal peptide capable of localizing the protein to the secretory pathway by SignalP, a signal sequence prediction program (Nielsen, H. *et al.*, 1997, *Protein Eng.* 10(1): 1-6). Polypeptides beginning at the first methionine are not predicted to contain a signal sequence; however, the consensus for signal prediction is only 80-90% accurate for known signal sequences. A third possibility for a translational start is that the cDNA listed in FIG. 1 is incomplete and another methionine is encoded in frame and upstream of the sequence shown in FIG.1. Further research demonstrated that third possibility was correct and the full length sequences are presented in FIG. 11A.

5.2.1.2. Extracellular Domain

If the predicted membrane spanning stretches do indeed function as transmembrane domains (see 5.2.1.3), then the putative CLASP extracellular domains are

characterized by one cadherin EC-like motif (Pigott, R. and Power, C., 1993, The Adhesion Molecule Factbook. Academic Press, pg. 6; Jackson, R. M. and Russell, R. B., 2000, J. Mol. Biol. 296: 325-34). Several highly conserved cysteines are found in the extracellular domain, as well as various glycosylation signals. Through its putative extracellular domains, CLASP proteins may interact with ligands in a homotypic and/or heterotypic manner to establish the immunological synapse in conjunction with molecules such as TCR, MHC class I, MHC class II, CD3 complex and accessory molecules such as CD4, CD3, ICAM-1, LFA-1, and others. Many cadherins contain a pro-domain of approximately 50 to 150 amino acids that is removed before localization to the plasma membrane. This cleavage is presumed to be carried out by Furin (Posthaus, H. *et al.*, 1998, FEBS Let 438: 306-10) at a consensus sequence of RKQR. Furin is a protease that is at least partially responsible for the maturation of certain cadherins. CLASP-2 has the sequence RNQR at nucleotides 854 through 865 (Figure 1). By homology, this region is around 120 amino acids into the predicted protein start site for hCLASP-2A. This region may be a pro-domain and cleavage may be required for CLASP function, or aspects of CLASP function.

Antibodies raised against the extracellular domain can be added to cells expressing CLASPs. These antibodies can either block the interaction of CLASP-2 with potential ligands or stabilize these interactions. Any immunoassay known in the art, *e.g.*, listed and described herein, may be used to assess the modulation of immune function brought about by this approach.

Similarly, portions of the extracellular domain of CLASP can be expressed as soluble protein. This soluble protein can then be added to cells expressing CLASP. These proteins may interact with potential ligands to competitively inhibit their binding to endogenous CLASPs. This could modulate CLASP function via the immunoassays described herein. Recombinant proteins could interfere in a positive or negative fashion with CLASP interactions.

5.2.1.3. Transmembrane Domain

CLASP predicted amino acid sequences were analyzed using the PHDhtm analysis software for prediction of transmembrane helices (Rost, B., *et al.*, 1996, Prot. Science 7: 1704-1718). Using the PPHDhtm analysis software, it was determined that there is a predicted transmembrane domain for CLASP-2 located from nucleotides 2861-2917 (see FIG. 1), as well as three other potential transmembrane domains located near the amino terminal end. These have not been verified experimentally, and are not clearly functioning as

membrane spanning regions. The presence of a N-terminal PH domain in certain CLASPs suggest that these proteins are membrane associated through that domain and are less likely to utilize membrane spanning regions.

5.2.1.4. Intracellular Domains

5 The CLASP intracellular domains contain motifs corresponding to several types of protein domains. Depending on the specific CLASP (*i.e.*, specific family member or splice variant) all or only some of the domains can be present. Listed from amino terminus to carboxy terminus, the domains include: (1) ITAM (Chan *et al.* 1994, *Annual Review of Immunology* 12: 555-592), (2) a newly discovered DOCK/CLASP motif, (3) one or two
10 coiled-coil motifs, and (4) a C-terminal PDZ binding motif (PBM) (also referred to as PDZ ligand or “PL”).

5.2.1.5. ITAM

 Immunoreceptor Tyrosine-based Activation Motifs (ITAM motifs; also known as ARAM, or antigen recognition activation motifs) are motifs contained within antigen
15 receptors for T and B cells, and Fc receptors on other leukocytes, and are necessary for proper activation and signal transduction in these cells. They are characterized by the consensus sequence YXXL/I - X7/8- YXXL/I (Grucza *et al.*, 1999, *Biochemistry* 38: 5024-5033), usually separated by 6-8 amino acids (Watson *et al.*, 1998, *Immunol. Today* 19: 260-264; Isakov, J. *Leukoc. Biol.* 61: 6-16). ITAM is used as an intracellular regulatory motif
20 through its ability to be tyrosine phosphorylated by src-family tyrosine kinases such as Lyn that are involved in leukocyte signal transduction. Once phosphorylated, the ITAM acts as a high affinity binding site for SH2 containing proteins. Signal transduction components including ZAP-70, Syk, Lyn, Shc, PI3 kinase, and Grb2 contain SH2 domains and have been shown to bind ITAMs (Clements *et al.*, 1999, *Annu. Rev. Immunol.* 17: 89-108). This
25 places ITAM-containing molecules in a central role of intracellular signal regulation in leukocytes. ITAM motifs in leukocyte signaling can facilitate signal transduction (*e.g.*, tyrosine kinase signaling) by acting as temporal scaffolds where other transduction components could bind and be properly positioned to mediate transduction. ITAM motifs often appear in multiples in a protein, however, it is known that one set of YXXL/I alone can
30 transduce signals of the PTK pathway, though weakly.

CLASP proteins typically have ITAM YXXL/I motifs (where X is any amino acid) separated by 3 or 13 amino acids. In various embodiments the CLASP-2 polypeptide of the invention is characterized by one or more of the motifs shown in Table 1.

Table 1

CLASP-2 ITAM Motifs

Motif No.	Sequence Motif
1	YXX(I/L)-X ₃ -YXX(I/L)
2	YXX(I/L)-X ₁₃ -YXX(I/L)
3	YXX(I/L)-X ₃ -YXX(I/L)-X ₁₃ -YXX(I/L)

The presence of multiple ITAM motifs in CLASP proteins indicates that they may be engaged by multiple signal transduction components (*e.g.*, ZAP-70/Syk, Shc, PI3 kinase, and Grb2). In general, the ITAM motif in CLASP proteins match identically to the canonical ITAM motif with some motifs containing a conservative amino acid change (*i.e.* valine instead of isoleucine or leucine). As previously described for other ITAMs, the ITAMs within CLASPs can bind SH2-containing proteins including ZAP-70, Syk, Shc, PI3 kinase, and Grb2. Since CLASPs have an extracellular domain, CLASPs protein can independently initiate a signal transduction cascade through engagement of its extracellular domain. Otherwise CLASPs may cooperate with an antigen receptor signaling complex (*e.g.*, with CD3/TCR, BCR, FcR), to facilitate tyrosine kinase signal transduction

The ITAMs have demonstrated different binding specificity and affinities for SH2 domains (Clements, *et al.*, 1999, Ann. Rev. Immunol. 17: 89-108). For example, Shc, PI3 kinase, and Grb2 bind to dual and mono phosphorylated ITAMs with different affinities. Thus the ITAMs in CLASPs are believed to provide quantitative as well as qualitative differences in signal transduction depending up their phosphorylation state, as well as to inhibit or augment specific protein interactions and hence specific tyrosine kinase-mediated signaling pathways in leukocytes.

Antagonizing the PTK-CLASP interactions (*e.g.*, phosphorylation of CLASP-2) will thus inhibit immune function. In one embodiment, interactions between ITAM-bearing human CLASPs and their binding partners are believed to be antagonized by the alpha subtype (SIRPalpha) of signal regulatory proteins that has been shown to negatively regulate ITAM-dependent lymphocyte activation (Lienard H; 1999, J Biol Chem 274: 32493-9). Also, a recently recognized family of immunoreceptor tyrosine-based inhibition motif (ITIM) receptors are thought to inhibit the ITAM-induced activation of immune competent

cells (Gergely, *et al.*, 1999, J. Immunol Lett 68: 3-15) and therefore may block CLASP-partner interactions.

5.2.1.6. DOCK

CLASP polypeptides contain a new “DOCK” motif, not previously described
5 in the scientific literature. The CLASP DOCK motif includes a series of five tyrosines surrounded by conserved sequences in regions A, B, C, D, and G (see FIG. 5B). There are also two highly conserved non-tyrosine containing regions (E and G) separated by nine amino acids (P+EXAI+XM) and (LXMXL+GXVXXXVNXG) (where X is any amino acid).

The region of CLASP proteins immediately following the ITAM motifs
10 exhibits sequence similarity to the C-terminal third of the so-called “DOCK” proteins. The DOCK gene family includes three molecules that are the human homologues of the *C. elegans* CED proteins known to be involved in apoptosis. CED-5 (DOCK180), a major CRK-binding protein, alters cell morphology upon translocation to the membrane (mediates the membrane motion that scavenger cells exhibit as they surround and engulf dying cells; its
15 function can be partially rescued by the human DOCK180 (Wu *et al.*, 1998, *Nature* 392: 501-504). Myoblast City in *Drosophila* (MBC) is another member of the DOCK protein family and has been found to be involved in myoblast fusion (Erickson, *et al.*, 1997, J. Cell Biol. 138: 589). Since CLASP-2 expression is found in syncytial tissues such as placenta, muscle, and heart, it is believed that CLASP-2 is involved in mediating or inhibiting cell fusion.

20 The DOCK family has been implicated in the control of cell shape. DOCK1, when transfected into spindle cells, can make them flattened and polygonal (Takai, *et al.*, 1996, *Genomics* 35: 403-303). DOCK1 expression is ubiquitous except in hematopoietic cells. DOCK2 is expressed in hematopoietic cells and when transfected into spindle cells can make them round up (Nishihara, H., 1999, *Hokkaido Igaku Zasshi* 74: 157-66). DOCK2 is
25 expressed in peripheral blood lymphocytes, thymus, spleen, and liver.

5.2.1.7. COILED-COIL

CLASPs have one to two predicted coiled-coil domains (Lupas *et al.*, 1991, *Science* 252: 1162-64; Lupas, A., 1996, *Meth. Enzymology* 266: 513-525). Coiled-coil domains are known to interact directly with cytoskeleton or other proteins, indicating that that
30 CLASP proteins may interact directly with the cytoskeleton. Thus, it is believed that CLASP proteins may bind cytoskeletal proteins, *e.g.*, spectrin, ankyrin, hsp70, talin, ezrin,

tropomyosin, myosin, plectin, syndecans, paralemmin, Band 3 protein, Cytoskeletal protein 4.1, Tyrosine phosphatase PTP36 and other molecules.

5.2.1.8. PDZ Ligand

Some CLASP proteins contain a PDZ-ligand motif (“PBM” or “PL”) at the C-terminus of the protein. This short (3 – 8 amino acid) motif mediates the binding of proteins terminating at their carboxyl terminus in the motif (most commonly S/T – X – V – free carboxyl-terminus) to other proteins containing one or more specific PDZ domains (See Songyang *et al.*, 1997, Science 275: 72 and Doyle *et al.*, 1996, Cell 85: 1067 for a discussion of PDZ-ligand structures).

PDZ domain-containing proteins are involved in the organization of ion channels and receptors at the neurological synapse and in establishing and maintaining polarity in epithelial cells via their binding to the C-termini of transmembrane receptors. It has been shown that PDZ-domain containing proteins can mediate protein-protein interactions in immune system cells (*e.g.*, DLG1 binds to the lymphocyte potassium channel KV1.3 in human T lymphocytes, (Hanada *et al.*, 1997, J. Biol. Chem. 272: 26899).

Biochemical evidence that CLASP-2 interacts with the PDZ domains of three closely related proteins is shown in FIG 9A-D. FIG. 9A demonstrates the specificity of the interaction, as the C-terminal 20 amino acids of CLASP-2 bind PSD-95, NeDLG, and DLG1, but not to the PDZ domains of the TIAM-1 protein. FIG. 9B demonstrates the affinity of the interaction. Notably, the highest affinity interaction occurs between CLASP-2 and NeDLG, with a specific binding affinity of at least 10^4 M^{-1} . Affinities in the micromolar range have been found for other biologically important PDZ-ligand interactions. FIG. 9C demonstrates the ability to inhibit CLASP-2 PDZ interactions using either a short fragment of CLASP-2 (the eight C-terminal amino acids) or the C-terminus of KV1.3. As noted above, KV1.3 is known to bind to DLG1 in live lymphocytes. FIG. 9D demonstrates that CLASP-2 and KV1.3 compete for PDZ binding; *i.e.*, not only does KV1.3 block CLASP-2 binding but CLASP-2 also blocks KV1.3 binding. The ability of the eight C-terminal residues of CLASP-2 to inhibit the interaction of both CLASP-2 and KV1.3 with selected PDZ domains suggests that compounds related to the C-terminal eight-amino acids of CLASP-2, when introduced into cells, will mediate changes in multiple protein-protein interactions involved in the function of lymphoid tissues and other tissues that express these proteins (including heart, lung, and kidney).

Evidence that the C-terminal 8 amino acids of CLASP-2, when introduced into cells, can effect cellular function comes from the experiments in which these amino acids were introduced into cells as a fusion, *e.g.*, with the HIV-derived TAT transporter peptide sequence. Addition of the TAT-CLASP-2 fusion peptide to Jurkat T lymphocytes (compared to controls using the TAT peptide alone) results in subtle, time-dependent alterations in intracellular calcium concentrations as measured using the calcium indicator dye Fluo-4. While these results are consistent with the hypothesis that the TAT-CLASP-2 fusion changes T cell ion fluxes. In particular, the results indicate that the CLASP-2 C-terminal sequence can slightly increase basal intracellular calcium concentrations and can slightly decrease the proportional increase in calcium upon activation of the cells with anti-CD3 antibody. Such changes would be expected for a compound that disrupts localization of the T cell activation-associated CLASP-2 protein and the KV1.3 potassium channel. Small changes in T cell calcium flux can result in large changes in the functional activity of the cells (Wulfing *et al.*, 1997, J. Exp. Med. 185: 1815). Of note, the brain alternatively spliced isoform KIAA1058 lacks the PDZ binding domain due to an alternative splice.

5.2.1.9. Modulation of Immune Responses

CLASP proteins, as described above, modulate immune function in a variety of ways and through a variety of mechanisms (*i.e.*, changing the threshold for T cell activation) by affecting formation of the immunological synapse. Establishment and maintenance of the immunological synapse can involve: (A) signal transduction, (B) cell-cell interactions, and (C) membrane organization.

(A) Signal transduction

Human CLASP proteins, as discussed above, may contain SH3 domains and tyrosine phosphorylation sites. These regions have been shown to be involved in signal transduction in a variety of cells including lymphocytes. Thus, human CLASP proteins are believed to interact with these regions during signal transduction events which lead to modulation of immune responses.

CLASP proteins can interact with Tec sub-family of nonreceptor tyrosine kinases. The Tec sub-family of nonreceptor tyrosine kinases consists of Tec, Btk, Tsk/Itk/Emt Itk, and Bmx, and is defined by the presence of SH3 and SH2 domains adjacent to the catalytic domain and an amino-terminal region containing a pleckstrin homology (PH) domain, a Tec homology (TH) domain, and a proline-rich region (Mano, H.; 1999, Cytokine

Growth Factor Rev 10: 267-80). The T cell specific Tsk/Itk/Emt, and Btk expressed in most hematopoietic cells other than T cells are important components of antigen receptor signaling pathways in hematopoietic cells.

Btk has been identified as the gene defective in murine X-linked immunodeficiency (*xid*) and human X-linked agammaglobulinemia (XLA) (Nisitani, S., 2000, Proc Natl Acad Sci U.S.A. 97: 2737-42). In *xid* mice, B cell numbers are reduced to one-half of normal and the titers of specific immunoglobulin isotypes are significantly reduced; in addition, *xid* B cells are insensitive to a number of mitogenic stimuli. The human disorder is much more severe, resulting in nearly complete elimination of the B cell compartment and dramatically reduced immunoglobulin levels. Biochemical studies have supported multiple roles for Btk in B cell activation. Btk kinase activity and tyrosine phosphorylation are increased after cross-linking either the B cell receptor on B cells or the high affinity IgE receptor, FcRI, on mast cells. Interleukin-5 and interleukin-6 treatment have also been shown to lead to the activation of Btk.

Itk, like Btk, is tyrosine-phosphorylated upon antigen receptor cross-linking (Mano, H., 1999, Cytokine Growth Factor Rev, 10: 267-80). In addition, peripheral T cells from mice lacking functional Itk are refractory to stimulation by antibodies to CD3 plus antigen presenting cells. These Itk-deficient T cells can be stimulated by phorbol ester and calcium ionophore, demonstrating that Itk acts in signaling pathways proximal to the TCR.

Unlike the related Src family tyrosine kinases including Lyn, Lck, Fyn, ZAP-70, SyK, and CSK, the Tec family kinases lack the amino-terminal myristylation site crucial for the membrane localization of Src family kinases, suggesting that some adaptor proteins are required for the their membrane localization (Mano, H., 1999, Cytokine Growth Factor Rev 10: 267-80). Since all the Tec family kinases contain a proline-rich region which could be bound by a SH3 domain, and since all the human CLASPs contain a putative SH3 domain, it is believed that human CLASPs could serve as adaptors for the members in the Tec family in different hematopoietic cells.

GTP-binding proteins play an important role in immune response (Mach, B., 1999, Science 285: 1367). A number of biochemical events triggered by TCR/CD3-induced T cell activation are ablated by agents that modulate the action of G proteins. Pertinent to this is the ability of cholera toxin to inhibit the cellular proliferation and intracellular Ca^{2+} mobilization that is mediated by anti-CD3 antibody treatment of T cells. The G protein competitive inhibitor GDPS, can impede the extent of inositol phosphates generated upon stimulation in peripheral T lymphocytes. Nonhydrolyzable analogs of GTP, such as

GTPgammaS, or other agents such as ALF that activate G proteins by circumventing the need for receptor engagement, can result in T cell activation.

The Gαq/11 subfamily (Stanners, J., 1995, J Biol Chem 270: 30635-42) and Rap1 (Lafont, V., 1998, Biochem Pharmacol 55: 319-24) of GTP-binding proteins have
5 been shown to be involved in human T cell receptor/CD3-mediated signal transduction pathway. Also, Cdc42, a Rho family small GTPase, is known to play a critical role in the formation of actin microspikes in response to external stimuli (Miki, H.; 1998, Nature, 391: 93-6). Interestingly, a Cdc42 binding protein, WASP, has a proline-rich domain which could interact with the SH3 domain present in all the human CLASPs. Human CLASPs may
10 interact with these GTP-binding proteins.

Several adaptor proteins including NCK, CBL (Bachmaier, K., 2000 Nature 403: 211-6), SHC, LNK, SLP-76, HS1, SIT, VAV, GrB2, and BRDG1, and two tyrosine phosphatases, EZRIN, SHP-1 and SHP-2 have been shown to interact with ITAM or SH3 domains. These proteins may also interact with CLASPs. Several proteins have been shown
15 to interact with ITAM or SH3 domains and may also interact with CLASP proteins. These include adaptor proteins such as NCK, CBL (Bachmaier, K., 2000, Nature 403: 211-6), SHC, LAT, LNK, SLP-76 (Krause M *et al.*, 2000, J Cell Biol 149: 181-94), HS1, SIT, VAV, GrB2 (Zhang W. and Samelson, L.E., 2000, Semin Immunol 12: 35-41), and BRDG1, kinases such as SYK and LCK, and tyrosine phosphatases such as SHP-1 and SHP-2. These
20 interactions can be defined by a number of different biochemical or cell biological methods including in vitro binding assays, co-immunoprecipitation assays, co-immunostaining (Harlow, E. and Lane, D., 1999, Using Antibodies: A laboratory Manual. Cold Spring Harbor Press) or genetic assays such as yeast the yeast two hybrid system, in which a CLASP protein or fragment can be used as “bait” (Zervos *et al.*, 1993, Cell 72: 223-232; Madura *et al.*, 1993, J. Biol. Chem 268: 12046-12054).
25

Other assays include in vitro binding assays, co-immunoprecipitation assays, co-immunostaining assays, and yeast two hybrid system screening assays in which a CLASP-2 domain or fragment can be used as “bait” or “trap” protein (Zervos *et al.* (1993), Cell 72: 223-232; Madura *et al.* (1993) J. Biol. Chem. 268: 12046-12054).

30 In other embodiments, CLASP polypeptides are transfected into lymphocytes. After transfection, a variety of standard assays can be used to evaluate, for example, CLASP modulation of T cell activation. These assays include calcium influx assays, NF-AT nuclear translocation assays (*e.g.*, Cell, 1998, 93: 851-61), NF-AT/luciferase reporter assays (*e.g.*,

MCB 1996 16: 7151-7160), tyrosine phosphorylation of early response proteins such as HS1, PLC- γ , ZAP-76, and Vav (*e.g.*, J. Biol. Chem. 1997, 272: 14562-14570).

(B) Cell-Cell Interaction

As discussed above, human CLASP proteins display homologous aspects of E-cadherin. As shown in FIG. 1, CLASP-2 contains both a cadherin cleavage domain and a cadherin ectodomain. Therefore CLASP proteins may interact with cadherins through these domains. The cadherins constitute a family of cell surface adhesion molecules that are involved in calcium-dependent cell to cell adhesion. Human cadherins, E-, P- N- and VE-cadherin, have a restricted tissue distribution: E- and P-cadherin are expressed in epithelial tissues, N-cadherin is found mainly on neural cells, and VE-cadherin is found on vascular endothelium. Homophilic binding between cadherins on adjacent cells is vital for the maintenance of strong cell to cell adhesion in these tissues. For example E-cadherin is required for the formation of adherens junctions between mature epithelial cells and is involved in Langerhans cell adhesion to keratinocytes, and VE-cadherin is needed for the maintenance of lateral association between endothelial cells. The extracellular regions of mature mammalian cadherins are comprised of five "CAD" modules of approximately 1110 amino acids. Crystallographic and biochemical studies indicate that cadherins can form dimers on the cell surface, and that interaction with dimeric cadherins on opposing cell surfaces can lead to the formation of "zipper-like" cell junctions.

The integrins are a second family of transmembrane adhesion molecules that are involved in both cell to cell and cell to matrix interactions. At least 15 chains associate with 8 chains to form a large number of heterodimeric integrins that can be classified into several major subfamilies based on their shared use of a particular chain. Members of three subfamilies, the 1, 2, and 7 integrins, are commonly found on leukocytes. The expression of 1 integrins is widespread (for example, 51, CD49e/CD29, is found on T cells, granulocytes, platelets, fibroblasts, endothelium, and epithelium), whereas the 2 and 7 integrins have a restricted pattern of expression.

Interestingly, E-cadherin on human epithelial cells has been found to be a ligand for the mucosal lymphocyte integrin, E7, and a similar interaction has been indicated in the mouse. Monoclonal antibodies to E-cadherin or to E7 block IEL adherence to epithelial cells, and transfection of cells with E7 confers upon them the ability to adhere to cells transfected with E-cadherin.

L929 cells can be transfected with CLASP and Neomycin. G418-resistant clones can be screened for CLASP-expression with anti-CLASP peptide-specific antibodies. CLASP-expressing clones can be used to test for homotypic and/or heterotypic calcium dependent cell adhesion using the “cell aggregation assay” described for cadherin molecules
5 (Murphy-Erdosh, C. *et al.*, 1995, J. Cell Biol. 129: 1379-1390).

Several approaches can be used to identify the amino acids involved in the binding domains. Soluble fusion molecules (*e.g.*, EC12-IgG, ECC-IgG, ECM-IgG, and GST-EC12), peptides, and peptide-specific anti-CLASP antibodies are available for blocking experiments in the above-described assay. Transfectants generated by site-directed
10 mutagenesis can also be used.

(C) Membrane Anchoring/Cytoskeletal Interactions

Interestingly, tyrosine-phosphorylated ITAMs interact with actin cytoskeleton upon activation of mature T lymphocytes (Rozdzial, M. M., 1995, Immunity 3: 623-633). Since human CLASPs contain both ITAMs and coiled-coil domains which have been shown
15 to interact with cytoskeletal proteins, CLASPs are believed to play an important role in modulating cell surface molecule expression by re-organizing cytoskeletal structure.

F-actin microfilament cytoskeletal organization has been known to be involved in the modulation of cell surface molecule expression. WASP, a GTPase-binding protein, plays a critical role in the formation of actin microspikes in response to external
20 stimuli and ectopic expression of WASP induces the formation of F-actin filament clusters that overlap with the expressed WASP itself. Another WASP family protein, N-WASP, has also been shown to play important roles in filopodium formation. Both of these proteins cause actin polymerization, but with different features when they are expressed in cells; WASP mainly localizes at perinuclear areas and causes actin clustering, but most N-WASP is
25 present at plasma membranes and induces filopodium formation (Miki, H.; 1998, Nature 391: 93-6). Both WASP and N-WASP, contain a proline-rich domain which could interact with the SH3 domain present in all the human CLASPs. CLASPs may interact with F-actin filament through CLASP protein binding to WASP or WASP-like proteins.

Standard assays can be used for detecting CLASP protein interaction with
30 cytoskeletal proteins. These assays include co-sedimentation assays, far western blot analysis (Ohba, T., 1998, Anal. Biochem. 262: 185-192), surface plasmon resonance, F-actin staining with phalloidin in CLASP-transfected lymphocytes (*e.g.*, Small, J. *et al.* 1999, Microsc. Res. Tech. 4: 3-17), and immunocytochemical analysis of subcellular distribution of focal adhesion

proteins (such as paxillin, tensin, vinculin, talin, and FAK in CLASP-transfected lymphocytes; see, *e.g.*, Ridyard, M.S., 1998, *Biochem. Cell Biol.* 76: 45-58).

5.2.2. CLASP-2 Exon Structure and Genomic Domains

Alternative splicing is likely to represent a regulatory switch that governs
5 different functions of CLASP proteins in immune responses. Additionally, alternative splice variants affecting the untranslated regions of an RNA can be a way of regulating RNA stability.

As noted *supra*, CLASP gene expression is characterized by alternative exon usage. Intron/exon structure can be predicted by computer analysis of genomic DNA,
10 however, splice junctions and alternative splicing can only be elucidated by comparison of genomic clones to cDNA clones. Alternative splicing and RNA editing are mechanisms generate a variety of proteins from the same gene. An example for how alternative splicing is used to generate thousands of different proteins from only a few genes is represented by the Neurexin gene family (for review of Neurexins, see Missler M. and Suedhof, T., 1998,
15 *Trends in Genetics*, 14: 20-25). Comparative analysis of CLASP-2 genomic clones and cDNA clones revealed that CLASP-2 is composed of numerous exons and that distinct CLASP-2 transcripts are generated by alternative splicing. The protein encoding portion of CLASP-2 is covered by at least 14 exons (FIG. 6A).

Numerous diseases are caused or are thought to be caused by splice site
20 mutations that can cause exon skipping or otherwise result in a truncated protein product. Some of these diseases include, *e.g.*, Marfan Syndrome (Liu W, et al., 1997, *Nat. Genet.* 16: 328-9), Hunter disease (Bonucelli G, et al., 2000, *Hum. Mutat.* (Online) 2000 15(4): 389, Duchenne muscular dystrophy (Wibawa T, et al., 2000, *Brain Dev.* 22(2): 107-112), Myelomonocytic leukemia (Wutz D, et al., 1999, *Leuk. Lymphoma* 35: 491-9.), and
25 Isovaleric acidemia (Vockley J, et al., 2000, *Am. J. Hum. Genet.* 66: 356-67). This is especially true for genes composed of many exons (such as CLASP genes). The genomic sequence around CLASP exon/intron boundaries is useful for diagnostic approaches towards the identification of diseases caused by splice site mutations. The abundance or presence of CLASP isoforms in cell populations (*e.g.*, hematopoietic cells, lymphocytes) is correlated
30 with a disease state by comparing the abundance of CLASP in cells from subjects suffering from the disease with the level of CLASP in cells from healthy subjects. This can be accomplished by utilizing any number of assays (*e.g.*, PCR).

Alignment of the CLASP-2 intron/exon splice sites with the CLASP-2 protein sequence and the finding of conserved exon/intron boundaries within the CLASP gene family (FIG. 6) suggest that specific CLASP-2 exons encode functionally distinct protein domains (see FIG. 6 and Example 4). ITAM and DOCK motifs 1 and 2 are encompassed by splice sites (amino acid residues 946 and 1063); DOCK motif 3 and COILED-COIL motif 1 and 2 are also encompassed by splice sites (amino acid residues 1102, 1170 and 1246, respectively).

CLASP-2 alternative transcripts are summarized in FIG. 3 and FIG. 11B. Briefly, one alternative exon missing in CLASP-2A is present in CLASP-2B and CLASP-2D. This exon contains the DNA portion encoding the ITAM motif and DOCK motif 1. The CLASP-2D protein product does not contain the C-terminal 38 amino acids of CLASP-2A and CLASP-2B: Thus, a PDZ binding motif (SSVV; amino acid residue 1286 through 1289) that is only present in the CLASP-2A/B-specific C-terminal end is missing in the CLASP-2D gene product. The presence or absence of this PDZ binding motif can be attributed to alternative RNA processing. Additionally, a CLASP-2 alternative transcript has been found that deletes nucleotides 209-291 that results in a premature stop codon. The protein encoded by this transcript appears to be a soluble form of CLASP-2 that may regulate (*e.g.*, is an antagonist or an agonist) the function other CLASP family members and isoforms.

5.2.3. CLASP Superfamily Members

As is illustrated in FIG. 5, CLASP-2 is a member of a superfamily of immune-cell associated proteins with similar motifs. CLASP-1 was described in U.S.S.N. 09/411,328, filed October 1, 1999. CLASP-1 uniquely among the known CLASPs contains SH3 binding domain motifs. CLASP-2A, -B, -C, and -E polypeptides have no adaptor binding sites or SH3 binding domains found in CLASP-1. CLASP-3, CLASP-4, CLASP-5 and CLASP-7 are described in copending U.S.S.N. 60/182,296, filed February 14, 2000, and which is incorporated by reference herein in its entirety for all purposes.

5.3. CLASP mRNA Expression

As described in Example 2, CLASP-2 mRNA expression was assayed in tissues and cell lines by Northern analysis. The results are shown in FIG. 4A and B. The results of Northern Analysis of CLASP expression and expression of other members of the CLASP family are summarized in Table 2.

Table 2

Tissue/Cell Line ¹	CLASP					
	1	2 ^{3,4}	3	4	5	7
PBL	+ ²	-	-	+++	++	-
Lung	-	+	-	-	-/+	+++
Placenta	-/+	+++	+	-/+	+	+
Sm Intestine	-/+	-	-	-	-/+	+

Kidney	-/+	+	+++	-/+	+	++
Spleen	++	-	-	-/+	+	-/+
Thymus	++	-	-	-/+	+	-
Colon	-	-	-	-	-	-
Skel Muscle	-	-/+	++	-	-	-/+
Heart	-/+	++	+++	-/+	-	+++
Brain	+++	-/+	-/+	-	-	-
Jurkat	++	++	++	+	-	-
MV411	++	-	++	+	+	+
THP1	++	-	-	-	-	-/+
HL60	-	-	-	-	-/+	-
9D10	++	++ ⁵	+	+	+	+
3A9	+	-/+	-	-	-	-
CH27	+	-/+	-	-	-	-
293	-	++	+++	+	-	+

1. Jurkat = human T cell line; MV4-11 = B myelomonocyte; 9D10 = B cell line; THP-1 = monocyte; 3A9 = mouse T cell; CH27 = mouse B cell line; HL60 = human promyelocyte; 293 = embryonic kidney epithelial cells (293)

2. Table Legend (based on Northern blot results): - = no expression; -/+ = low expression; + = medium expression; ++ medium high expression; +++ high expression.

3. A CLASP-2 EST (EST 815795) was identified from a bone marrow cDNA library.

4. The probe used (HC2.2) did not distinguish between CLASP-2A, -2B, -2C and 2D.. This probe encompasses nucleotides 3920 to 4650 (731 bp long) from CLASP-2A cDNA.

5. In RNA from 9D10, the major transcript runs substantially shorter than the major transcripts seen in Jurkat and 293 cells; however, the longer transcript is also present in 9D10. Hybridization of probe HC2.2 with 9D10 total RNA reveals at least 3 different transcripts. See FIG. 4B

As indicated in Table 2 and shown in FIG. 4, CLASP-2 is expressed most strongly in placenta followed by lung, kidney and heart; CLASP-3 is expressed strongly in kidney and heart, and less strongly in placenta and skeletal muscle ; CLASP-4 is expressed exclusively in peripheral blood lymphocytes; CLASP-5 is expressed strongly in peripheral blood leukocytes, present in placenta, kidney, spleen and thymus, and weakly in lung, small intestine and liver. It is not expressed in brain, heart, skeletal muscle and large intestine;

CLASP-7 is expressed strongly in lung, heart, liver and kidney, but not in PBL, brain or thymus.

Differences in tissue expression patterns for different CLASP proteins indicate different CLASPs have differential roles in immune function and, accordingly, can be separately targeted to achieve different functions. For example, since CLASP proteins are necessary for proper function or signaling by the T cell receptor (TCR), the tissue specific distribution of different CLASPs permits differential modulation of the immune response in different tissues. Since CLASP-2 is present in heart, blocking CLASP-2 function or expression is useful to selectively block immune response in the heart (for example, to selectively stop immune response in the heart compartment, *e.g.*, following cardiac transplant rejection or post-MI inflammation, without compromising immunity elsewhere. Similarly, blocking CLASP-3 can block rejection of the kidney following kidney transplant. Furthermore, by adjusting the level of inhibition, the degree of immune blockage versus response can be modulated in the compartments represented by each CLASP.

15 **5.4. CLASP Polynucleotides And Methods Of Use**

The present invention provides a variety of CLASP (*e.g.* CLASP-2) polynucleotides and methods for using them. In one aspect, the polynucleotide of the invention encodes a polypeptide comprising at least a fragment (*e.g.*, an immunogenic fragment) of a CLASP-2 protein (*e.g.*, at least a fragment of SEQ. ID. NO: 2, 4, 6 or 10) or
20 variant thereof. In another aspect, the molecules that comprise a CLASP-2 polynucleotide that, while not necessarily encoding a CLASP-2 protein or fragment, is useful as a probe or primer for detecting CLASP-2 expression, for inhibition of CLASP-2 expression (*e.g.*, antisense or ribozyme-mediated inhibition), for gene knockout, and the like.

5.4.1. CLASP Polynucleotides

25 The invention also provides isolated or purified nucleic acids having at least 8 nucleotides (*i.e.*, a hybridizable portion) of a CLASP sequence (*e.g.*, CLASP-2) or its complement; in other embodiments, the nucleic acids consist of at least about 25 (continuous) nucleotides, about 50 nucleotides, about 100 nucleotides, about 150 nucleotides, about 200 nucleotides, about 250 nucleotides, about 500 nucleotides, about 550 nucleotides, about 600
30 nucleotides, or about 650 nucleotides or more of a CLASP sequence, or a full-length CLASP coding sequence. In another embodiment, the nucleic acids are smaller than about 35, about

200 or about 500 nucleotides in length. Polynucleotides can be single or double stranded, and may be DNA, RNA, PNA or a hybrid molecule.

In specific aspects, nucleic acids are provided which comprise a sequence complementary to at least about 10, 25, 50, 100, 150, 200, 250, 500, 550, 600, or 650
5 nucleotides or the entire coding region of a CLASP coding sequence. Usually, the isolated polynucleotide is less than about 100 kbp, generally less than about 50 kbp, and often less than about 20 kbp, less than about 10 kbp, less than about 5 kbp, or less than about 1000 nucleotides in length.

In a specific embodiment, a nucleic acid that is hybridizable to a CLASP
10 nucleic acid or its complement, or to a nucleic acid encoding a CLASP derivative, under conditions of low stringency is provided. Derivatives of CLASP contemplated include, but are not limited to, splice variants of a gene encoding a CLASP, other members of a CLASP gene family which differ from one of the CLASP nucleotide or amino acid sequences disclosed herein by the insertion or deletion of one or several domains, and the like.

In one embodiment, the CLASP polynucleotide is identical or exactly
15 complementary to SEQ. ID NO: 1, 3, 5 or 9 or selectively hybridizes to an aforementioned sequence. In various embodiments, the polynucleotide is identical or exactly complementary to, or selectively hybridizes to, the nucleotide sequence encoding a particular protein domain or region, or a particular gene exon of the CLASP mRNA or genomic sequence. Such
20 polynucleotides are particularly useful as probes, because they can be selected to identify a defined species of CLASP.

In addition to the polypeptide and polynucleotide sequences specifically exemplified herein, the invention contemplates CLASP homologues from other species, allelic and splice variants, and other variants disclosed herein. The CLASP-2 gene exhibits
25 evidence of alternative splicing of transcripts.

For example, CLASP-2A and CLASP-2C are related to each other as apparent splice variants, with CLASP-2C containing an exon not found in CLASP-2A. The exon sequence is 5'-AGG GAT TTT GAG AGG CTG GCC CAT CTG TAT GAC ACG CTG CAC CGG GCC TAC AGC AAA GTG ACC GAG GTC ATG CAC TCG GGC CGC AGT
30 TNC TGG GGA CCT ACT TCC GGG TAG CCT TCT TCG GGC AG-3' (encoding the peptide sequence: RDFERLAHLYDTLHRAYSKVTEVMHSGRLLGTYFRVAFFGQGF). It will be apparent to one of skill that, by using polynucleotide probes or primers corresponding to the nucleic acid sequence above, or by using antibodies that specifically recognize the peptide above, or those polynucleotide probes or primers shown in Table 3

below, it is possible to distinguish between different CLASP isoforms(*e.g.*, to detect differential expression).

Table 3

	Found in/will detect	Exemplary Probe/Primer (5' – 3')	Notes/Comments
1	full length hC2A	F1: CCCAGATTTTATGATGAG R1: GATAATGACAAAGTTCTGAC	
2	full length hC2D	F2: CTGGAAATCTTGACAAAATGC R2: GTCTTTTAATACAGATGTGG	
3	hC2B, hC2C, hC2E	F3: GAGAGGCTGGCCCATCTGTATG R3: ATCTTCAAAGAATCCCTGCC	Distinction based upon product size differences following PCR
4	hC2D	F4: GAAGCAGTCCAGTGGGAGCCG R4: GCCTCCCGGCTCCTCCTCAGG	Recognizes hC2D-specific insertion
5	hC2D	F3: GAGAGGCTGGCCCATCTGTATG R5: CCTCCACATCTGTTCACTGTC	
6	hC2E	F5: CTCCATGATGGAAGACGTGGG R6: GATGAGCTCGTAGCGCTCGGC	Spans deletion unique to hC2E. Distinction based upon product size differences following PCR
7	hC2B	F6: CATTGGCGTTTAAGCTCCTG R3: ATCTTCAAAGAATCCCTGCC	F6 primer spans deletion unique to hC2E
8	hC2A	F7: GGACCCATAGTTTCATGATCG R4: CTTTCATCTTCAAGAAATCCCTC	R4 primer spans the region where other CLASPs have an insert

5 **5.4.1.1. Substantial Identity**

In some embodiments, the CLASP polynucleotides of the invention are substantially identical to SEQ ID NOs: 1, 3, 5, or 9, or to a fragment thereof.

An indication that two nucleic acid sequences are substantially identical is that the two polynucleotides have a specified percentage sequence identity *e.g.*, usually at least about 75%, at least about 80%, at least about 85%, at least about 90%, at least about 95%, or at least about 98 identity over a specified region when optimally aligned.

Another indication that two nucleic acid sequences are substantially identical is that a polypeptide encoded by the first nucleic acid is immunologically cross reactive with the antibodies raised against the polypeptide encoded by the second nucleic acid, as described below. Thus, a polypeptide is typically substantially identical to a second polypeptide, for example, where the two peptides differ only by conservative substitutions. Another indication that two nucleic acid sequences are substantially identical is that the two molecules or their complements hybridize to each other under stringent conditions, as described below.

Yet another indication that two nucleic acid sequences are substantially identical (*e.g.*, a naturally occurring allele of the CLASP sequence of SEQ ID NO: 1) is that the same primers can be used to amplify the sequence. For example, CLASP-2 polynucleotides can be PCR amplified from cDNA derived from human lymphocytes using the primer pairs shown in Table 3.

The primers of Table 3 are also useful for amplification of CLASP-2 splice variants. Another indication that two nucleic acid sequences are substantially identical is that they selective hybridize under stringent conditions (*i.e.*, one sequence hybridizes to the complement of the second sequence), as described *infra*.

10 **5.4.1.2. Selective Hybridization**

The invention also relates to nucleic acids that selectively hybridize to exemplified CLASP-2 sequences (including hybridizing to the exact complements of these sequences). Selective hybridization can occur under conditions of high stringency (also called “stringent hybridization conditions”), moderate stringency, or low stringency.

15 **5.4.1.2.1. High Stringency**

“Stringent hybridization conditions” are conditions under which a probe will hybridize to its target subsequence, typically in a complex mixture of nucleic acid, but not to other sequences. Stringent conditions are sequence-dependent and will be different in different circumstances. Longer sequences hybridize specifically at higher temperatures. An extensive guide to the hybridization of nucleic acids is found in Tijssen, Techniques in Biochemistry and Molecular Biology--Hybridization with Nucleic Probes, “Overview of principles of hybridization and the strategy of nucleic acid assays” (1993). Generally, stringent conditions are selected to be about 5-10°C lower than the thermal melting point (T_m) for the specific sequence at a defined ionic strength pH. The T_m is the temperature (under defined ionic strength, pH, and nucleic concentration) at which 50% of the probes complementary to the target hybridize to the target sequence at equilibrium (as the target sequences are present in excess, at T_m , 50% of the probes are occupied at equilibrium). Stringent conditions will be those in which the salt concentration is less than about 1.0 M sodium ion, typically about 0.01 to 1.0 M sodium ion concentration (or other salts) at pH 7.0 to 8.3 and the temperature is at least about 30°C for short probes (*e.g.*, 10 to 50 nucleotides) and at least about 60°C for long probes (*e.g.*, greater than 50 nucleotides). Stringent conditions may also be achieved with the addition of destabilizing agents such as formamide.

For high stringency hybridization, a positive signal is at least two times background, preferably 10 times background hybridization. Exemplary high stringency or stringent hybridization conditions include: 50% formamide, 5x SSC and 1% SDS incubated at 42° C or 5x SSC and 1% SDS incubated at 65° C, with a wash in 0.2x SSC and 0.1% SDS at 65° C. In
5 a specific embodiment, a nucleic acid which is hybridizable to a CLASP-2 nucleic acid under the following conditions of high stringency is provided: Prehybridization of filters containing DNA is carried out for 8 h to overnight at 65°C in buffer composed of 6X SSC, 50 mM Tris-HCl (pH 7.5), 1 mM EDTA, 0.02% PVP, 0.02% Ficoll, 0.02% BSA, and 500 µg/ml denatured salmon sperm DNA. Filters are hybridized for 8-16 h at 65°C in prehybridization
10 mixture containing 100 µg/ml denatured salmon sperm DNA and 5-20 X 10⁶ cpm of ³²P-labeled probe. Washing of filters is done at 65°C for 15-30 h in a solution containing 2X SSC, 0.1% SDS. This is followed by a wash in 0.2X SSC and 0.1% at 50°C for 15-30 min before autoradiography.

5.4.1.2.2. Moderate Stringency

15 In another specific embodiment, a nucleic acid, which is hybridizable to a CLASP-2 nucleic acid under conditions of moderate stringency is provided. Examples of procedures using such conditions of moderate stringency are as follows: Filters containing DNA are pretreated for 6 h at 55°C in a solution containing 6X SSC, 5X Denhart's solution, 0.5% SDS and 100 µg/ml denatured salmon sperm DNA. Hybridizations are carried out in
20 the same solution and 5-20 X 10⁶ cpm ³²P-labeled probe is used. Filters are incubated in hybridization mixture for 12-16 h at 55°C, and then washed twice for 30 minutes at 50°C in a solution containing 1X SSC and 0.1% SDS. Filters are blotted dry and exposed for autoradiography. Other conditions of moderate stringency which can be used are well-known in the art. Washing of filters is done at 45°C for 1 h in a solution containing 0.2X SSC and
25 0.1% SDS.

5.4.1.2.3. Low Stringency

By way of example and not limitation, procedures using such conditions of low stringency are as follows (see also Shilo and Weinberg, 1981, Proc. Natl. Acad. Sci. U.S.A. 78: 6789-6792): Filters containing DNA are pretreated for 6 h at 40 C in a solution
30 containing 35% formamide, 5X SSC, 50 mM Tris-HCl (pH 7.5), 5 mM EDTA, 0.1% PVP, 0.1% Ficoll, 1% BSA, and 500 µg/ml denatured salmon sperm DNA. Hybridizations are

carried out in the same solution with the following modifications: 0.02% PVP, 0.02% Ficoll, 0.2% BSA, 100 g/ml salmon sperm DNA, 10% (wt/vol) dextran sulfate, and $5-20 \times 10^6$ cpm ^{32}P -labeled probe is used. Filters are incubated in hybridization mixture for 18-20 h at 40 C, and then washed for 1.5 h at 55 C in a solution containing 2X SSC and 0.1% SDS. The wash
5 solution is replaced with fresh solution and incubated an additional 30 minutes at 50-55°C. Filters are blotted dry and exposed for autoradiography. If necessary, filters are washed for a third time at 60-65°C and reexposed to film. Other conditions of low stringency that can be used are well known in the art (*e.g.*, as employed for cross-species hybridizations).

5.4.1.3. CLASP Variants and Fragments

10 The CLASP variants of the invention can contain alterations in the coding regions, non-coding regions, or both. Especially preferred are polynucleotide variants containing alterations which produce silent substitutions, additions, or deletions, but do not alter the properties or activities of the encoded polypeptide. Nucleotide variants produced by
15 polynucleotide variants can be produced for a variety of reasons, *e.g.*, to optimize codon expression for a particular host (change codons in the human mRNA to those preferred by a bacterial host such as *E. coli*).

Exemplary CLASP polynucleotide fragments are preferably at least about 15 nucleotides, and more preferably at least about 20 nucleotides, still more preferably at least
20 about 30 nucleotides, and even more preferably, at least about 40 nucleotides in length, or larger 50, 150, 200, 250, 300, 350, 400, 450, 500, 550, 600, 650 nucleotides. In one embodiment, exemplary fragments include fragments having at least a sequence from about nucleotide number 1-50, 51-100, 101-150, 151-200, 201-250, 251-300, 301-350, 351-400, 401-450, 451-500, 501-550, 551-600 to the end of any sequence shown in the figures or in
25 the sequence listing or comprising the cDNA coding sequence in the deposited clones. In this context "about" includes the particularly recited ranges, larger or smaller by several (5, 4, 3, 2, or 1) nucleotides, at either terminus or at both termini. Preferably, these fragments encode a polypeptide which has biological activity. More preferably, these polynucleotides can be used as probes or primers as discussed herein.

30 In other embodiments, CLASP-2 polynucleotides of the invention are other than SEQ ID NO:1 or fragments of SEQ ID NO:1.

As shown in FIG 11 above, there are at least three CLASP-2 full length cDNA isoforms (A + Z, B + Z, and C + Z). Each of the isoforms uses a unique first exon (labelled exon 1A, 1B, and 1C) (*see* FIG. 11 and Table 4 below).

Table 4: CLASP-2 Isoforms

CLASP-2 Isoform	FIG 11C Schematic	Nucleotides
Isoform 1	A + Z	-182 to 6690
Isoform 2	B + Z	-219 to 6690
Isoform 3	C + Z	-143 to 6690

5

In one embodiment, the CLASP-2 polynucleotide has the sequence shown in FIG. 11 (Isoform 1, Isoform 2, or Isoform 3 as indicated in Table 4 above) or a fragment of the sequence shown in FIG. 11 comprising at least about 1, 5, 10, 25 or 50 or more contiguous nucleotides from nucleotides -182 to 1883 of Isoform 1, nucleotides -219 to 1883 of Isoform 2, or nucleotides -143 to 1883 of Isoform 3.

In another embodiment, CLASP-2 primers or probes comprise at least about 5, 10, 25 or 50 or more contiguous nucleotides from nucleotides -182 to 1883 of Isoform 1, nucleotides -219 to 1883 of Isoform 2, or nucleotides -143 to 1883 of Isoform 3 as shown in FIG. 11 and Table 4 above alone or in combination with SEQ ID NO:1 or a fragment of SEQ ID NO:1.

In an aspect, the invention provides antibodies or binding fragments that bind the CLASP. In another embodiment, the invention provides antibodies that specifically bind to the CLASP-2 isoforms shown in FIG. 11 but not to the polypeptide encoded by SEQ ID NO:1

In one embodiment, the CLASP variants differ from those shown in FIG. 1 or FIG. 11 (SEQ ID NOs 1, 3, 5, 7 9, etc_) by virtue of incorporating a different combination of exons than found in the exemplified sequences. For example, 81g01 (Genbank Accession Number AF85864; Locus HUMYN81g01; 526 bp; EST sequence submitted August 29, 1998 by Washington University at St. Louis; *see* FIG. 3A and FIG. 3B) is a variant of hCLASP-2 on the basis of CLASP-2 identity along certain stretches of the sequence. From 5' to 3', it begins with a 315 nucleotide stretch which is identical to CLASP-2A. It then has a gap relative to CLASP-2A that is identical to the GAP in another CLASP-2 isoform, hCLASP-2D (KIAA1058). In place of that gap, a 16 amino acid insert (48 nucleotides) is present which is not found in other isoforms, followed by another approximately 150 bp stretch of nucleotides

once again identical to CLASP-2A. This is characteristic of an alternate splice due to the specific sequence identity on both sides of a differential stretch of nucleotides.

Using known methods of protein engineering and recombinant DNA technology, variants can be generated to improve or alter the characteristics of the CLASP polypeptides. For instance, one or more amino acids can be deleted from the N-terminus or C-terminus of the CLASP-2 protein without substantial loss of biological function.

Furthermore, even if deleting one or more amino acids from the N-terminus or C-terminus of a polypeptide results in modification or loss of one or more biological functions, other biological activities can still be retained. For example, the ability of a deletion variant to induce and/or to bind antibodies which recognize the secreted form will likely be retained when less than the majority of the residues of the secreted form are removed from the N-terminus or C-terminus. Whether a particular polypeptide lacking N- or C-terminal residues of a protein retains such immunogenic activities can readily be determined by routine methods described herein and otherwise known in the art.

Thus, the invention further includes CLASP polypeptide variants which show biological activity. Such variants include deletions, insertions, inversions, repeats, and substitutions selected according to general rules known in the art so as to have little effect on activity. For example, guidance concerning how to make phenotypically silent amino acid substitutions is provided in Bowie, J. U. *et al.*, Science 247: 1306-1310 (1990), wherein the authors indicate that there are two main strategies for studying the tolerance of an amino acid sequence to change.

The first strategy exploits the tolerance of amino acid substitutions by natural selection during the process of evolution. By comparing amino acid sequences in different species, conserved amino acids can be identified. These conserved amino acids are likely important for protein function. In contrast, the amino acid positions where substitutions have been tolerated by natural selection indicate that these positions are not critical for protein function. Thus, positions tolerating amino acid substitution could be modified while still maintaining biological activity of the protein.

The second strategy uses genetic engineering to introduce amino acid changes at 30 specific positions of a cloned gene to identify regions critical for protein function. For example, site directed mutagenesis or alanine-scanning mutagenesis (introduction of single alanine mutations at every residue in the molecule) can be used. (Cunningham and Wells, 1989, Science 244: 1081-1085) The resulting mutant molecules can then be tested for biological activity.

In various embodiments, CLASP-2 polynucleotide fragments include coding regions for, or regions hybridizable to, the CLASP-2 structural or functional domains described *supra*. As set out in the Figures, such preferred regions include the following domains/motifs: ITAM, DOCK, COILED/COILED, and PBM. Thus, for example, polypeptide fragments of CLASP-2 as shown in FIG. 1 and FIG. 11-(SEQ ID NO: 2, 4, 6 10, etc.,) falling within conserved domains are specifically contemplated by the present invention (see FIG. 3). Moreover, polynucleotide fragments encoding these domains are also contemplated. Such polypeptide fragments find use, for example, as inhibitors of CLASP-2 function in CLASP-2-expressing cells.

10 **5.4.2. Uses of CLASP-2 Polynucleotides**

The CLASP polynucleotides of the invention are useful in a variety of applications. In one aspect of the invention, the polypeptide-encoding CLASP polynucleotides of the invention are used to express CLASP polypeptides (*e.g.*, as described herein) for example to produce anti-CLASP-antibodies or for use as therapeutic polypeptides. In another aspect, the CLASP polynucleotide or fragments thereof can be used for diagnostic purposes (*e.g.*, as probes for CLASP-2 expression). In particular, since CLASPs can be expressed in lymphocytes, a CLASP polynucleotide can be used to detect the expression of CLASP as a lymphocyte marker. For diagnostic purposes, a CLASP polynucleotide can be used to detect CLASP gene expression or aberrant CLASP gene expression in disease states. In another aspect, the CLASP polynucleotide or fragments are used for therapeutic purposes. For example, included in the scope of the invention are methods for inhibiting CLASP expression, *e.g.*, using oligonucleotide sequences, such as antisense RNA and DNA molecules and ribozymes, that function to inhibit expression of CLASP. In another aspect, CLASP polynucleotides can be used to construct transgenic and knockout animals, *e.g.*, for screening of CLASP agonists and antagonists. In another aspect, CLASP polynucleotides can be used for screening of CLASP agonists and antagonists.

5.4.2.1. Use of CLASP-2 Polynucleotides for Detection, Diagnosis, and Treatment

The CLASP polynucleotides of the invention are useful for detection of CLASP expression in cells and in the diagnosis of diseases or disorders (*e.g.*, immunodeficient states) resulting from aberrant expression of the CLASP. For example, aberrant expression of CLASP mRNA or protein means expression in lymphocytes (*e.g.*, T lymphocytes or B lymphocytes) or other CLASP expressing cells of at least 2-fold, preferably

at least 5-fold greater or less than expression in control lymphocytes obtained from a healthy subject. CLASP polypeptide expression is easily measured by ELISA using anti-CLASP antibodies of the invention. CLASP mRNA expression (including expression of specific species or splice variants of CLASP) can be measured by quantitative Northern analysis or
5 quantitative PCR, LCR, or other methods, using the probes and primers of the invention.

In one embodiment, the assays of the present invention are amplification-based assays for detection of an CLASP-2 gene product. In an amplification based assay, all or part of a CLASP-2 mRNA or cDNA (hereinafter also referred to as "target") is amplified, and the amplification product is then detected directly or indirectly. When there is no
10 underlying gene product to act as a template, no amplification product is produced (*e.g.*, of the expected size), or amplification is non-specific and typically there is no single amplification product. In contrast, when the underlying gene or gene product is present, the target sequence is amplified, providing an indication of the presence and/or quantity of the underlying gene or mRNA. Target amplification-based assays are well known to those of
15 skill in the art.

The present invention provides a wide variety of primers and probes for detecting CLASP-2 genes and gene products. Such primers and probes are sufficiently complementary to the CLASP-2 gene or gene product to hybridize to the target nucleic acid. Primers are typically at least 6 bases in length, usually between about 10 and about 100 bases,
20 typically between about 12 and about 50 bases, and often between about 14 and about 25 bases in length, often PCR primers of 15-30 (*e.g.*, 18-22 nucleotides) are used. However, the length of primers can be adjusted by one skilled in the art. One of skill, having reviewed the present disclosure, will be able, using routine methods, to select primers to amplify all, or any portion, of the CLASP-2 gene or gene product, or to distinguish between variant gene
25 products, CLASP-2 alleles, and the like. Single oligomers (*e.g.*, U.S. Pat. No. 5,545,522), nested sets of oligomers, or even a degenerate pool of oligomers can be employed for amplification.

It will be appreciated that probes and primers can be selected to distinguish between species and splice variants based on the guidance of this disclosure, by targeting
30 primers or probes to differentially used exons (or exon-exon junctions that differ between variants).

Methods can include the steps of collecting a sample of cells from a patient, isolating nucleic acid (*e.g.*, genomic, mRNA or both) from the cells of the sample, contacting the nucleic acid sample with one or more primers which specifically hybridize to an CLASP-

2 gene under conditions such that hybridization and amplification of the CLASP-2-gene (if present) occurs, and detecting the presence or absence of an amplification product, or detecting the size of the amplification product and comparing the length to a control sample. See U.S. Pat. Nos. 4,683,195 and 4,683,202, Landegran *et al.*, 1988, Science 241: 1077-1080; 5 Nakazawa *et al.*, 1994, Proc. Natl. Acad. Sci. U.S.A. 91: 360-364, Abravaya *et al.*, 1995, Nucleic Acids Res. 23: 675-682).

Because CLASP-2 gene products are expressed in the immune system (*e.g.*, T lymphocytes, B lymphocytes and macrophages), expression will be typically assayed in these cells. Methods which are well known to those skilled in the art can be used to isolate 10 lymphocytes, macrophages, and alike (*See, e.g.*, Coligan, J. E., *et al.* (eds.), 1991, Current Protocols in Immunology, John Wiley & Sons, NY; this reference is incorporated by reference for all purposes). In one embodiment, assays are carried out on biopsy or autopsy-derived tissue.

In various embodiments, CLASP-2 gene expression is detected by 15 hybridization of a detectable probe to mRNA or cDNA obtained from cells (*e.g.*, lymphocytes). A variety of methods for specific DNA and RNA measurement using nucleic acid hybridization techniques are known to those of skill in the art (see Sambrook *et al.*, *supra*). Hybridization based assays refer to assays in which a probe nucleic acid is hybridized to a target nucleic acid, forming a hybridization complex. Usually the nucleic 20 acid hybridization probes of the invention are entirely or substantially identical to a contiguous sequence of the CLASP-2 gene or RNA sequence. Preferably, nucleic acid probes are at least about 50 bases, often at least about 20 bases, and sometimes at least about 200 bases, at least about 300-500 nucleotides or more in length. Various hybridization techniques are well known in the art, and are in fact the basis of many commercially available 25 diagnostic kits.

Methods of selecting nucleic acid probe sequences for use in nucleic acid hybridization are discussed in Sambrook *et al.*, *supra*. In some formats, at least one of the target and probe is immobilized. The immobilized nucleic acid can be DNA, RNA, or another oligo- or poly-nucleotide, and can comprise natural or non-naturally occurring 30 nucleotides, nucleotide analogs, or backbones. Such assays can be in any of several formats including: Southern, Northern, dot and slot blots, high-density polynucleotide or oligonucleotide arrays (*e.g.*, GeneChipsTM Affymetrix), dip sticks, pins, chips, or beads. All of these techniques are well known in the art and are the basis of many commercially available diagnostic kits. Hybridization techniques are generally described in Hames *et al.*,

ed., 1985, *Nucleic Acid Hybridization, A Practical Approach* IRL Press; Gall and Pardue, 1969, *Proc. Natl. Acad. Sci. U.S.A.*, 63: 378-383; and John *et al.*, 1969, *Nature*, 223: 582-587.

5 A variety of nucleic acid hybridization formats are known to those skilled in the art. For example, one common format is direct hybridization, in which a target nucleic acid is hybridized to a labeled, complementary probe. Typically, labeled nucleic acids are used for hybridization, with the label providing the detectable signal. One method for evaluating the presence, absence, or quantity of CLASP-2 mRNA is carrying out a Northern transfer of RNA from a sample and hybridization of a labeled CLASP-2 specific nucleic acid probe. A useful method for evaluating the presence, absence, or quantity of DNA encoding CLASP-2 proteins in a sample involves a Southern transfer of DNA from a sample and hybridization of a labeled CLASP-2 specific nucleic acid probe.

Other common hybridization formats include sandwich assays and competition or displacement assays. Sandwich assays are commercially useful hybridization assays for detecting or isolating nucleic acid sequences. Such assays utilize a “capture” nucleic acid covalently immobilized to a solid support and a labeled “signal” nucleic acid in solution. The biological or clinical sample will provide the target nucleic acid. The “capture” nucleic acid and “signal” nucleic acid probe hybridize with the target nucleic acid to form a “sandwich” hybridization complex. To be effective, the signal nucleic acid cannot hybridize with the capture nucleic acid.

20 In one embodiment, CLASP polypeptides or polynucleotides are useful in treating deficiencies or disorders of the immune system, by activating or inhibiting the activation, differentiation of immune cells. Immune cells develop through a process called hematopoiesis, producing myeloid (platelets, red blood cells, neutrophils, and macrophages) and lymphoid (B and T lymphocytes) cells from pluripotent stem cells. The etiology of these immune deficiencies or disorders can be genetic, somatic, such as cancer or some autoimmune disorders, acquired (*e.g.*, by chemotherapy or toxins), or infectious.

In another embodiment, CLASP-2 polynucleotides or polypeptides are useful in treating or detecting deficiencies or disorders of hematopoietic cells. CLASP-2 polypeptides or polynucleotides could be used to increase differentiation and proliferation of hematopoietic cells, including the pluripotent stem cells, in an effort to treat those disorders associated with a decrease in certain (or many) types hematopoietic cells. Examples of immunologic deficiency syndromes include, but are not limited to: blood protein disorders (*e.g.*, agammaglobulinemia, dysgammaglobulinemia), ataxia telangiectasia, common variable

immunodeficiency, DiGeorge Syndrome, HIV infection, HTLV-BLV infection, leukocyte adhesion deficiency syndrome, lymphopenia, phagocyte bactericidal dysfunction, severe combined immunodeficiency (SCIDs), Wiskott-Aldrich Disorder, anemia, thrombocytopenia, or hemoglobinuria.

5 In one embodiment, CLASP-2 polynucleotides or polypeptides are useful in treating or detecting autoimmune diseases. The term “autoimmune disease” as used herein has the normal meaning in the art and refers to a spontaneous or induced malfunction of the immune system of mammals in which the immune system fails to distinguish between foreign immunogenic substances within the mammal and/or autologous (“self”) substances and, as a result, treats autologous (“self”) tissues and substances as if they were foreign and mounts an immune response against them. Autoimmune disease is characterized by production of either antibodies that react with self tissue, and/or the activation of immune effector T cells that are autoreactive to endogenous self antigens. Three main immunopathologic mechanisms act to mediate autoimmune diseases: 1) autoantibodies are directed against functional cellular receptors or other cell surface molecules, and either stimulate or inhibit specialized cellular function with or without destruction of cells or tissues; 2) autoantigen--autoantibody immune complexes form in intercellular fluids or in the general circulation and ultimately mediate tissue damage; and 3) lymphocytes produce tissue lesions by release of cytokines or by attracting other destructive inflammatory cell types to the lesions. These inflammatory cells in turn lead to production of lipid mediators and cytokines with associated inflammatory disease.

 Since many autoimmune disorders result from inappropriate recognition of self as foreign material by immune cells. This inappropriate recognition results in an immune response leading to the destruction of the host tissue. Therefore, the administration of CLASP-2 polypeptides or polynucleotides that can inhibit an immune response, particularly the proliferation, or differentiation of T-cells, can be an effective therapy in preventing autoimmune disorders.

 Examples of autoimmune disorders that can be treated or detected by CLASP-2 include, but are not limited to: Addison’s Disease, hemolytic anemia, antiphospholipid syndrome, rheumatoid arthritis, dermatitis, allergic encephalomyelitis, glomerulonephritis, Goodpasture’s Syndrome, Graves’ Disease, Multiple Sclerosis, Myasthenia Gravis, Neuritis, Ophthalmia, Bullous Pemphigoid, Pemphigus, Polyendocrinopathies, Purpura, Reiter’s Disease, Stiff-Man Syndrome, Autoimmune Thyroiditis, Systemic Lupus Erythematosus,

Autoimmune Pulmonary Inflammation, Guillain-Barre Syndrome, insulin dependent diabetes mellitus, and autoimmune inflammatory eye disease.

Similarly, allergic reactions and conditions, such as asthma (particularly allergic asthma) or other respiratory problems, can also be treated by CLASP-2 polypeptides or polynucleotides. Moreover, CLASP-2 can be used to treat anaphylaxis or hypersensitivity to an antigenic molecules.

In one embodiment CLASP-2 polynucleotides or polypeptides are used to treat and/or prevent organ rejection or graft-versus-host disease (GVHD). Organ rejection occurs by host immune cell destruction of the transplanted tissue through an immune response. Similarly, an immune response is also involved in GVHD, but, in this case, the foreign transplanted immune cells destroy the host tissues. The administration of CLASP-2 polypeptides or polynucleotides that inhibits an immune response, particularly the proliferation, differentiation of T-cells, can be an effective therapy in preventing organ rejection or GVHD.

Similarly, in another embodiment, CLASP-2 polypeptides or polynucleotides are used to modulate inflammation. The term “inflammation” refers to both acute responses (*i.e.*, responses in which the inflammatory processes are active) and chronic responses (*i.e.*, responses marked by slow progression and formation of new connective tissue). Acute and chronic inflammation can be distinguished by the cell types involved. Acute inflammation often involves polymorphonuclear neutrophils; whereas chronic inflammation is normally characterized by a lymphohistiocytic and/or granulomatous response. Inflammation includes reactions of both the specific and non-specific defense systems. A specific defense system reaction is a specific immune system reaction response to an antigen (possibly including an autoantigen). A non-specific defense system reaction is an inflammatory response mediated by leukocytes incapable of immunological memory. Such cells include granulocytes, macrophages, neutrophils and eosinophils.

For example, CLASP-2 polypeptides or polynucleotides can inhibit the proliferation and differentiation of cells involved in an inflammatory response. These molecules can be used to treat inflammatory conditions, both chronic and acute conditions, including inflammation associated with infection (*e.g.*, septic shock, sepsis, or systemic inflammatory response syndrome (SIRS)), ischemia-reperfusion injury, endotoxin lethality, arthritis, complement-mediated hyperacute rejection, nephritis, cytokine or chemokine induced lung injury, inflammatory bowel disease, Crohn’s disease, or resulting from over production of cytokines (*e.g.*, TNF or IL-1.). Examples of specific types of inflammation are

diffuse inflammation, focal inflammation, croupous inflammation, interstitial inflammation, obliterative inflammation, parenchymatous inflammation, reactive inflammation, specific inflammation, toxic inflammation and traumatic inflammation.

5 In another embodiment CLASP-2 polypeptides or polynucleotides are used to treat or detect infectious agents. For example, by increasing the immune response, particularly increasing the proliferation and differentiation of B and/or T cells, infectious diseases can be treated. The immune response can be increased by either enhancing an existing immune response, or by initiating a new immune response. CLASP-2 polypeptides or polynucleotides can be used to treat or detect any of these symptoms or diseases.

10 **5.4.2.2. Use of CLASP Polynucleotides in Screening**

The presence or absence of hCLASP nucleotide and amino acid sequences in a biological sample can be used in screening assays as medical diagnostics to aid in clinical decision-making. In one embodiment, hCLASP-based diagnostics involves screening assays for vaginal bleeding of unknown cause. In several examples discussed below, the cause of the bleeding can be in part differentiated by knowledge of whether the vaginal bleeding contains placental components (Hart FD, Ed., 1985, French's Index of Differential Diagnosis, 12th Ed. John Wright & Sons, pp. 561-63). In these cases, the high expression of hCLASP nucleotide sequences in placenta relative to its low expression in blood (FIG. 4A) will allow the detection of the presence of placenta based on the presence of the hCLASP nucleotide or protein. Such detection can be achieved by quantitative RT-PCR, Northern analysis, Western analysis, ELISAs, and fluorescence activated cell sorting (FACS) by using labeled anti-hCLASP-2 antibodies (Sambrook *et al.*, 1989, Molecular Cloning, 2nd Ed., Cold Spring Harbor Lab. Press; Harlow *et. al.*, 1988, Antibodies, a laboratory manual, Cold Spring Harbor Lab. Press).

25 For example, hCLASP can be used in the following screening assays:

(1) A woman gives birth and presents with post-partum bleeding. In this case the presence of placental tissue indicates a condition called "retained products of conception" that requires surgical evacuation of the uterus (Decherney and Pernol, Eds., 1996, Current Obstetric & Gynecologic Diagnosis & Treatment, 8th Ed. McGraw Hill).

30 (2) A pregnant woman suffers from vaginal bleeding of unknown origin. In this case the presence of placental tissue indicates a condition called "threatened

abortion” that implies a poor prognosis for carrying the fetus to term (Decherney and Pernol, Eds., 1996, Current Obstetric & Gynecologic Diagnosis & Treatment, 8th Ed. McGraw Hill).

(3) A woman of child bearing age presents with vaginal bleeding and is found to have a positive pregnancy test without evidence of an intra-uterine pregnancy. In this case, the most serious of the differential diagnoses is ectopic pregnancy, a medical emergency. However, another common diagnosis is a completed abortion or miscarriage. The presence of products of conception (*i.e.* placenta) in the vaginal bleeding strongly favors the diagnosis of completed abortion over that of ectopic pregnancy (Decherney and Pernol, Eds., 1996, Current Obstetric & Gynecologic Diagnosis & Treatment, 8th Ed. McGraw Hill).

In another embodiment, hCLASP-2-based diagnostics involve screening assays to determine injury to vital tissues that express hCLASP-2 at high levels. Such tissues include kidney, heart, and lung (Fig 4A). Injury to these tissues can result in leakage of cells and cellular constituents including hCLASP-2 into surrounding fluids (specified below). Detection of abnormally high levels of hCLASP-2 protein in these surrounding fluids by Western analysis or ELISA, or detection of abnormally high levels of hCLASP-2 RNA in these fluids by RT-PCR or Northern analysis is expected to aid in the diagnosis of tissue injury.

In the case of renal injury, the hCLASP-2 nucleotide or amino acid sequences or fragments thereof would be expected to appear in the urine. Detection of abnormally high levels of hCLASP-2 can aid in the diagnosis of both nephritis and tubular necrosis, and differentiate from non-renal causes of proteinuria. Early diagnosis of nephritis is of particular value in patients with clinical signs and symptoms suggestive of systemic lupus erythematosus in whom early diagnosis and treatment of lupus nephritis can prevent irreversible kidney damage (Cameron J.S., 1999, J Nephrol 12 Suppl 2: S29-41). While tubular necrosis currently cannot be reversed by pharmacotherapy, differentiation of tubular necrosis from pre-renal failure is critical in formulating a treatment plan for oligouric hospitalized patients (Bidani A. and Churchill P.C., 1989, Dis Mon 35: 57-132).

In the case of myocardial injury, the hCLASP-2 nucleic or amino acid sequence or fragments thereof are expected to appear in the blood. This is analogous to current standard practice of monitoring for other elevated levels myocardial proteins (*e.g.*, creatine kinase, troponin) in the blood following myocardial infarction and ischemia by standard ELISA or electrophoretic methodologies (Fauci *et al.*, (eds.), 1998, Harrison’s Principles of Internal Medicine, 14th Ed., McGraw Hill, pp. 1352-1375). The presence of

hCLASP-2 in cardiac muscle and its absence in skeletal muscle and blood makes hCLASP-2 an ideal marker to diagnose and monitor myocardial injury.

Unlike myocardial injury, pulmonary injury is not routinely diagnosed by assaying serum for lung-specific proteins. By analogy to myocardial infarction, pulmonary infarction also releases lung-specific proteins and cells into systemic circulation. Pulmonary infarction due to pulmonary embolism (PE) or pneumonia is expected to release hCLASP-2-bearing cells or protein/peptides into systemic circulation. Detection of hCLASP-2 protein in serum or RNA in blood can aid in the diagnosis of pulmonary infarction in the appropriate clinical setting. Current methods to diagnose PE are not only expensive but lack specificity and sensitivity, and the misdiagnosis of this condition is a leading cause of preventable death in hospitalized patients (Raskob G.E. and Hull R.D., 1999, *Curr Opin Hematol.* 6(5): 280-4).

In another embodiment, hCLASP-2-based diagnostics involve screening assays for identifying disorders of cells of hematopoietic lineage. hCLASP-2 is expressed in human T cells, B cells but not cells from the myeloid lineage. Different hCLASP-2 isoforms in T and B cells permit further discrimination between malignancies of T and B lineage (FIG. 4B). Precise identification of hematopoietic cell types is vital to guide chemotherapy and radiation therapy of patients with leukemia and lymphoma (Fauci et al Eds., 1998, *Harrison's Principles of Internal Medicine*, 14th Ed. McGraw Hill, pp. 695-712). hCLASP-2 expression differences can be detected by using FACS, immunofluorescence, immunoperoxidase staining, RT-PCR, in situ hybridization or RNA blot analysis (Sambrook, Fritsch and Maniatis, *Molecular Cloning*, 2nd Ed. Cold Spring Harbor Lab. Press, 1989; Ward MS, *Pathology* 1999 Nov; 31(4): 382-92).

In another embodiment, hCLASP-2-based diagnostics involve screening assays for identifying activated immune system cells. Although hCLASP-2 is generally expressed at quite low levels in PBMCs (which is critical for some of the above applications), it is known that the surface expression of the closely related mouse CLASP-1 protein is altered during the process of lymphocyte activation. An analogous change in expression is expected for the hCLASP-2 protein. Subtyping lymphocytes specific for a particular antigen, for example, using MHC-based multimeric staining reagents (Altman et. al., 1996, *Science* 274: 94-6), for separating cell populations into hCLASP-2 high and hCLASP-2 low populations, can aid in determining the nature of the immune response against that antigen. Such understanding is critical, for example, in predicting the course of chronic viral infections such as hepatitis B, hepatitis C, and HIV, and to designing appropriate treatment regimens for patients suffering from these infections.

hCLASP-2 can also serve as a potential therapeutic agent for Wilms' tumor. Wilms tumor is the most common primary renal tumor of childhood (Cotran, Kumar, and Collins, 1999, Robbins Pathologic Basis of Disease, 6th Ed. W.B. Saunders, pp. 487-89). As discussed herein, hCLASP-2 is highly expressed in 293 cells, embryonic kidney epithelial cells. Therefore, hCLASP-2 nucleic or amino acid sequence or fragments can serve as tumor markers for Wilms' tumor. Antibodies directed against a hCLASP-2 variant that is expressed only in Wilms' tumor can serve as novel therapeutic agents for Wilms' tumor, and can also function as delivery vehicles for other targeted therapeutics that may be attached to the anti-hCLASP-2 antibody (*e.g.*, chemotherapeutics or radiolabeling).

10 **5.4.2.2.1. CLASP Antisense, Ribozyme and Triplex Polynucleotides and Methods of Use**

Oligonucleotide sequences, that include anti-sense RNA and DNA molecules and ribozymes that function to inhibit the translation of a CLASP-2 mRNA are within the scope of the invention. Such molecules are useful in cases where downregulation of CLASP-2 expression is desired. Anti-sense RNA and DNA molecules act to directly block the translation of mRNA by binding to targeted mRNA and preventing protein translation. The invention provides methods and antisense oligonucleotide or polynucleotide reagents which can be used to reduce expression of CLASP-2 gene products *in vitro* or *in vivo*. Administration of the antisense reagents of the invention to a target cell results in reduced CLASP activity. As will be apparent to one of skill and as discussed *supra* (Table 3), specific CLASP-2 splice variants can be specifically targeted for inhibition. Alternatively, by designing an, *e.g.*, antisense molecule that recognizes a sequence found in several or all CLASP-2 species, a general inhibition can be achieved.

A. Antisense

Without intending to be limited to any particular mechanism, it is believed that antisense oligonucleotides bind to, and interfere with the translation of, the sense CLASP-2 mRNA. Alternatively, the antisense molecule can render the CLASP-2 mRNA susceptible to nuclease digestion, interfere with transcription, interfere with processing, localization or otherwise with RNA precursors ("pre-mRNA"), repress transcription of mRNA from the CLASP-2 gene, or act through some other mechanism. However, the particular mechanism by which the antisense molecule reduces CLASP-2 expression is not critical.

The antisense polynucleotides of the invention comprise an antisense sequence of at least 7 to 10 to typically 20 or more nucleotides that specifically hybridize to a sequence

from mRNA encoding CLASP-2 or mRNA transcribed from the CLASP-2 gene. More often, the antisense polynucleotide of the invention is from about 10 to about 50 nucleotides in length or from about 14 to about 35 nucleotides in length. In other embodiments, antisense polynucleotides are polynucleotides of less than about 100 nucleotides or less than about 200 nucleotides. In general, the antisense polynucleotide should be long enough to form a stable duplex but short enough, depending on the mode of delivery, to administer in vivo, if desired. The minimum length of a polynucleotide required for specific hybridization to a target sequence depends on several factors, such as G/C content, positioning of mismatched bases (if any), degree of uniqueness of the sequence as compared to the population of target polynucleotides, and chemical nature of the polynucleotide (*e.g.*, methylphosphonate backbone, peptide nucleic acid, phosphorothioate), among other factors. Generally, to assure specific hybridization, the antisense sequence is substantially complementary to the target CLASP-2 mRNA sequence. In certain embodiments, the antisense sequence is exactly complementary to the target sequence. The antisense polynucleotides can also include, however, nucleotide substitutions, additions, deletions, transitions, transpositions, or modifications, or other nucleic acid sequences or non-nucleic acid moieties so long as specific binding to the relevant target sequence corresponding to CLASP-2 RNA or its gene is retained as a functional property of the polynucleotide.

It will be appreciated that the CLASP-2 polynucleotides and oligonucleotides of the invention can be made using nonstandard bases (*e.g.*, other than adenine, cytidine, guanine, thymine, and uridine) or nonstandard backbone structures to provides desirable properties (*e.g.*, increased nuclease-resistance, tighter-binding, stability or a desired T_m). Techniques for rendering oligonucleotides nuclease-resistant include those described in PCT publication WO 94/12633. A wide variety of useful modified oligonucleotides may be produced, including oligonucleotides having a peptide-nucleic acid (PNA) backbone (Nielsen *et al.*, 1991, Science 254: 1497) or incorporating 2'-O-methyl ribonucleotides, phosphorothioate nucleotides, methyl phosphonate nucleotides, phosphotriester nucleotides, phosphorothioate nucleotides, phosphoramidates. Still other useful oligonucleotides may contain alkyl and halogen-substituted sugar moieties comprising one of the following at the 2' position: OH, SH, SCH₃, F, OCN, OCH₃OCH₃, OCH₃O(CH₂)_nCH₃, O(CH₂)_nNH₂ or O(CH₂)_nCH₃, where n is from 1 to about 10; C₁ to C₁₀ lower alkyl, substituted lower alkyl, alkaryl or aralkyl; Cl; Br; CN; CF₃; OCF₃; O-, S-, or N-alkyl; O-, S-, or N-alkenyl; SOCH₃; SO₂CH₃; ONO₂; NO₂; N₃; NH₂; heterocycloalkyl; heterocycloalkaryl; aminoalkylamino; polyalkylamino; substituted silyl; an RNA cleaving group; a cholesteryl group; a folate

group; a reporter group; an intercalator; a group for improving the pharmacokinetic properties of an oligonucleotide; or a group for improving the pharmacodynamic properties of an oligonucleotide and other substituents having similar properties. Folate, cholesterol or other groups that facilitate oligonucleotide uptake, such as lipid analogs, may be conjugated

5 directly or via a linker at the 2' position of any nucleoside or at the 3' or 5' position of the 3'-terminal or 5'-terminal nucleoside, respectively. One or more such conjugates may be used. Oligonucleotides may also have sugar mimetics such as cyclobutyls in place of the pentofuranosyl group. Other embodiments may include at least one modified base form or "universal base" such as inosine, or inclusion of other nonstandard bases such as queosine

10 and wybutosine as well as acetyl-, methyl-, thio- and similarly modified forms of adenine, cytidine, guanine, thymine, and uridine which are not as easily recognized by endogenous endonucleases. The antisense oligonucleotide can comprise at least one modified base moiety which is selected from the group including, but not limited to, 5-fluorouracil, 5-bromouracil, 5-chlorouracil, 5-iodouracil, hypoxanthine, xanthine, 4-acetylcytosine,

15 5-(carboxyhydroxymethyl) uracil, 5-carboxymethylaminomethyl-2-thiouridine, 5-carboxymethylaminomethyluracil, dihydrouracil, beta-D-galactosylqueosine, inosine, N6-isopentenyladenine, 1-methylguanine, 1-methylinosine, 2,2-dimethylguanine, 2-methyladenine, 2-methylguanine, 3-methylcytosine, 5-methylcytosine, N6-adenine, 7-methylguanine, 5-methylaminomethyluracil, 5-methoxyaminomethyl-2-thiouracil, beta-

20 D-mannosylqueosine, 5'-methoxycarboxymethyluracil, 5-methoxyuracil, 2-methylthio-N6-isopentenyladenine, uracil-5-oxyacetic acid (v), wybutoxosine, pseudouracil, queosine, 2-thiocytosine, 5-methyl-2-thiouracil, 2-thiouracil, 4-thiouracil, 5-methyluracil, uracil-5-oxyacetic acid methylester, uracil-5-oxyacetic acid (v), 5-methyl-2-thiouracil, 3-(3-amino-3-N-2-carboxypropyl) uracil, (acp3)w, and 2,6-diaminopurine.

25 The invention further provides oligonucleotides having backbone analogues such as phosphodiester, phosphorothioate, phosphorodithioate, methylphosphonate, phosphoramidate, alkyl phosphotriester, sulfamate, 3'-thioacetal, methylene(methylimino), 3'-N-carbamate, morpholino carbamate, chiral-methyl phosphonates, nucleotides with short chain alkyl or cycloalkyl intersugar linkages, short chain heteroatomic or heterocyclic

30 intersugar ("backbone") linkages, or CH₂-NH-O-CH₂, CH₂-N(CH₃)-OCH₂, CH₂-O-N(CH₃)-CH₂, CH₂-N(CH₃)-N(CH₃)-CH₂ and O-N(CH₃)-CH₂-CH₂ backbones (where phosphodiester is O-P-O-CH₂), or mixtures of the same. Also useful are oligonucleotides having morpholino backbone structures (U.S. Patent No. 5,034,506).

Useful references include *Oligonucleotides and Analogues, A Practical Approach*, edited by F. Eckstein, IRL Press at Oxford University Press (1991); *Antisense Strategies*, Annals of the New York Academy of Sciences, Volume 600, Eds. Baserga and Denhardt (NYAS 1992); Milligan *et al.*, 9 July 1993, J. Med. Chem. 36(14): 1923-1937; 5 *Antisense Research and Applications* (1993, CRC Press), in its entirety and specifically Chapter 15, by Sanghvi, entitled "Heterocyclic base modifications in nucleic acids and their applications in antisense oligonucleotides;" and *Antisense Therapeutics*, ed. Sudhir Agrawal (Humana Press, Totowa, New Jersey, 1996).

In one embodiment, the antisense sequence is complementary to relatively 10 accessible sequences of the CLASP-2 mRNA (*e.g.*, relatively devoid of secondary structure). This can be determined by analyzing predicted RNA secondary structures using, for example, the MFOLD program (Genetics Computer Group, Madison WI) and testing in vitro or in vivo as is known in the art. Another useful method for identifying effective antisense compositions uses combinatorial arrays of oligonucleotides (see, *e.g.*, Milner *et al.*, 1997, Nature 15 Biotechnology 15: 537). Examples of oligonucleotides that can be tested in cells for antisense suppression of CLASP-2 function are those capable of hybridizing to (*i.e.*, substantially complementary to) the following positions from SEQUENCE ID NO: 1:

- 1) GAAGGCGATCATCACGTGGCCTTCCATCGC
- 2) GCTTCAAGTAATGACTGGTGCAGAACATCTG
- 20 3) GCTCCTCCTCAGGCAGGCGCTATGGCTGTGG
- 4) GTAGGCCCGGTGCAGCGTGTACATACAGATGG

(See also Example 8)

In some embodiments, administration of antisense oligonucleotides will result in reduction of hCLASP-mRNA expression by at least about 50%, as assessed by Northern 25 analysis after administration of an antisense phosphorothioate oligonucleotide at a concentration of 1 μ M, 5 μ M, 10 μ M or 20 μ M.

The invention also provides an antisense polynucleotide that has sequences in addition to the antisense sequence (*i.e.*, in addition to anti-CLASP-2-sense sequence). In this case, the antisense sequence is contained within a polynucleotide of longer sequence. In 30 another embodiment, the sequence of the polynucleotide consists essentially of, or is, the antisense sequence.

The antisense nucleic acids (DNA, RNA, modified, analogues, and the like) can be made using any suitable method for producing a nucleic acid, such as the chemical synthesis and recombinant methods disclosed herein. In one embodiment, for example, antisense RNA molecules of the invention can be prepared by *de novo* chemical synthesis or by cloning. For example, an antisense RNA that hybridizes to CLASP-2 mRNA can be made by inserting (ligating) an CLASP-2 DNA sequence (*e.g.*, SEQUENCE ID No: 1, or fragment thereof) in reverse orientation operably linked to a promoter in a vector (*e.g.*, plasmid). Provided that the promoter and, preferably termination and polyadenylation signals, are properly positioned, the strand of the inserted sequence corresponding to the noncoding strand will be transcribed and act as an antisense oligonucleotide of the invention. The term “operably linked” refers to a functional linkage between a nucleic acid expression control sequence (such as a promoter or enhancer) and a second nucleic acid sequence, wherein the expression control sequence directs transcription of the nucleic acid corresponding to the second sequence.

In one embodiment, antisense DNA oligodeoxyribonucleotides derived from the translation initiation site, *e.g.*, between -10 and +10 regions of a CLASP-2 nucleotide sequence, are used. For general methods relating to antisense polynucleotides, see ANTISENSE RNA AND DNA, 1988, D.A. Melton, Ed., Cold Spring Harbor Laboratory, Cold Spring Harbor, NY). See also, Dagle *et al.*, 1991, Nucleic Acids Research, 19: 1805. For a review of antisense therapy, see, *e.g.*, Uhlmann *et al.*, 1990, Chem. Reviews, 90: 543-584.

B. Ribozyme

Ribozymes are enzymatic RNA molecules capable of catalyzing the specific cleavage of RNA. The mechanism of ribozyme action involves sequence specific hybridization of the ribozyme molecule to complementary target RNA, followed by endonucleolytic cleavage. Within the scope of the invention are engineered hammerhead motif ribozyme molecules that specifically and efficiently catalyze endonucleolytic cleavage of CLASP-2 RNA sequences.

Specific ribozyme cleavage sites within any potential RNA target are initially identified by scanning the target molecule for ribozyme cleavage sites which include the following sequences, GUA, GUU and GUC. Once identified, short RNA sequences of between 15 and 20 ribonucleotides corresponding to the region of the target gene containing the cleavage site can be evaluated for predicted structural features such as secondary structure that can render the oligonucleotide sequence unsuitable. The suitability of candidate targets

can also be evaluated by testing their accessibility to hybridization with complementary oligonucleotides, using ribonuclease protection assays.

C. Triplex

Alternatively, endogenous target gene expression can be reduced by targeting
5 deoxyribonucleotide sequences complementary to the regulatory region of the target gene
(*i.e.*, the target gene promoter and/or enhancers) to form triple helical structures that prevent
transcription of the target gene in target cells in the body. (See generally, Helene, 1991,
Anticancer Drug Des., 6(6): 569-584; Helene *et al.*, 1992, Ann. N.Y. Acad. Sci., 660: 27-36;
and Maher, 1992, Bioassays 14(12): 807-815).
10 Nucleic acid molecules to be used in triplex helix formation for the inhibition
of transcription should be single stranded and composed of deoxynucleotides. The base
composition of these oligonucleotides must be designed to promote triple helix formation via
Hoogsteen base pairing rules, which generally require sizable stretches of either purines or
pyrimidines to be present on one strand of a duplex. Nucleotide sequences can be
15 pyrimidine-based, which will result in TAT and CGC⁺ triplets across the three associated
strands of the resulting triple helix. The pyrimidine-rich molecules provide base
complementarity to a purine-rich region of a single strand of the duplex in a parallel
orientation to that strand. In addition, nucleic acid molecules can be chosen that are purine-
rich, for example, contain a stretch of G residues. These molecules will form a triple helix
20 with a DNA duplex that is rich in GC pairs, in which the majority of the purine residues are
located on a single strand of the targeted duplex, resulting in GGC triplets across the three
strands in the triplex.

Alternatively, the potential sequences that can be targeted for triple helix
formation can be increased by creating a so called "switchback" nucleic acid molecule.
25 Switchback molecules are synthesized in an alternating 5'-3', 3'-5' manner, such that they
base pair with first one strand of a duplex and then the other, eliminating the necessity for a
sizable stretch of either purines or pyrimidines to be present on one strand of a duplex.

D. General

The anti-sense RNA and DNA molecules, ribozymes and triple helix
30 molecules of the invention can be prepared by any method known in the art for the synthesis
of RNA molecules. These include techniques for chemically synthesizing
oligodeoxyribonucleotides well known in the art such as for example solid phase
phosphoramidite chemical synthesis. Alternatively, RNA molecules can be generated by *in*
vitro and *in vivo* transcription of DNA sequences encoding the antisense RNA molecule.

Such DNA sequences can be incorporated into a wide variety of vectors which contain suitable RNA polymerase promoters such as the T7 or SP6 polymerase promoters. Alternatively, antisense cDNA constructs that synthesize antisense RNA constitutively or inducibly, depending on the promoter used, can be introduced stably into cell lines.

5 Various modifications to the DNA molecules can be introduced as a means of increasing intracellular stability and half-life. Possible modifications include, but are not limited to, the addition of flanking sequences of ribo- or deoxy- nucleotides to the 5' and/or 3' ends of the molecule or the use of phosphorothioate or 2' O-methyl rather than phosphodiesterase linkages within the oligodeoxyribonucleotide backbone.

10 Methods for introducing polynucleotides into such cells or tissue include methods for *in vitro* introduction of polynucleotides such as the insertion of naked polynucleotide, *i.e.*, by injection into tissue, the introduction of a CLASP-2 polynucleotide in a cell *ex vivo*, the use of a vector such as a virus, (*e.g.*, a retrovirus, adenovirus, adeno-associated virus, and the like), phage or plasmid, and the like or techniques such as
15 electroporation or calcium phosphate precipitation.

5.4.2.2.2. Gene Therapy

By introducing gene sequences into cells, gene therapy can be used to treat conditions in which the cells do not express normal CLASP-2 or express abnormal/inactive CLASP-2. In some instances, the polynucleotide encoding a CLASP-2 is intended to replace
20 or act in the place of a functionally deficient endogenous gene. Alternatively, abnormal conditions characterized by overexpression can be treated using the gene therapy techniques described below.

In a specific embodiment, nucleic acids comprising a sequence encoding a CLASP-2 protein or functional derivative thereof, are administered to promote CLASP-2
25 function, by way of gene therapy. Gene therapy refers to therapy performed by the administration of a nucleic acid to a subject. In this embodiment of the invention, the nucleic acid produces its encoded protein that mediates a therapeutic effect by promoting CLASP-2 function.

Any of the methods for gene therapy available in the art can be used according
30 to the present invention. Exemplary methods are described below.

For general reviews of the methods of gene therapy, *see*, Goldspiel *et al.*, 1993, Clinical Pharmacy 12: 488-505; Wu and Wu, 1991, Biotherapy 3: 87-95; Tolstoshev, 1993, Ann. Rev. Pharmacol. Toxicol. 32: 573-596; Mulligan, 1993, Science 260: 926-932;

and Morgan and Anderson, 1993, Ann. Rev. Biochem. 62: 191-217; Can, 1993, TIBTECH 11(5): 155-215). Methods commonly known in the art of recombinant DNA technology which can be used are described in Ausubel *et al.*, *supra*; and Kriegler, 1990, Gene Transfer and Expression, A Laboratory Manual, Stockton Press, NY.

5 In one aspect, the therapeutic composition comprises a CLASP-2 nucleic acid that is part of an expression vector that encodes a CLASP-2 protein or fragment or chimeric protein thereof in a suitable host. In particular, such a nucleic acid has a promoter operably linked to the CLASP-2 coding region, said promoter being inducible or constitutive, and, optionally, tissue-specific. In another particular embodiment, a nucleic acid molecule is used
10 in which the CLASP-2 coding sequences and any other desired sequences are flanked by regions that promote homologous recombination at a desired site in the genome, thus providing for intrachromosomal expression of the CLASP-2 nucleic acid (Koller and Smithies, 1989, Proc. Natl. Acad. Sci. U.S.A. 86: 8932-8935; Zijlstra *et al.*, 1989, *Nature* 342: 435-438).

15 Delivery of the nucleic acid into a patient can be either direct, in which case the patient is directly exposed to the nucleic acid or nucleic acid-carrying vector, or indirect, in which case, cells are first transformed with the nucleic acid *in vitro*, then transplanted into the patient. These two approaches are known, respectively, as *in vivo* or *ex vivo* gene therapy.

20 In a specific embodiment, the nucleic acid is directly administered *in vivo*, where it is expressed to produce the encoded product. This can be accomplished by any of numerous methods known in the art, *e.g.*, by constructing it as part of an appropriate nucleic acid expression vector and administering it so that it becomes intracellular, *e.g.*, by infection using a defective or attenuated retroviral or other viral vector (*see*, U.S. Patent No.
25 4,980,286), or by direct injection of naked DNA, or by use of microparticle bombardment (*e.g.*, a gene gun; Biolistic, Dupont), or coating with lipids or cell-surface receptors or transfecting agents, encapsulation in liposomes, microparticles, or microcapsules, or by administering it in linkage to a peptide which is known to enter the nucleus, by administering it in linkage to a ligand subject to receptor-mediated endocytosis (*see, e.g.*, Wu and Wu,
30 1987, J. Biol. Chem. 262: 4429-4432) (which can be used to target cell types specifically expressing the receptors), and the like. In another embodiment, a nucleic acid-ligand complex can be formed in which the ligand comprises a fusogenic viral peptide to disrupt endosomes, allowing the nucleic acid to avoid lysosomal degradation. In yet another embodiment, the nucleic acid can be targeted *in vivo* for cell specific uptake and expression,

by targeting a specific receptor (*see, e.g.*, PCT Publications WO 92/06180 dated April 16, 1992; WO 92/22635 dated December 23, 1992; WO 92/20316 dated November 26, 1992; WO 93/14188 dated July 22, 1993; WO 93/20221 dated October 14, 1993). Alternatively, the nucleic acid can be introduced intracellularly and incorporated within host cell DNA for expression, by homologous recombination (Koller and Smithies, 1989, Proc. Natl. Acad. Sci. U.S.A. 86: 8932-8935; Zijlstra *et al.*, 1989, Nature 342: 435-438).

In a specific embodiment, a viral vector that contains the CLASP-2 nucleic acid is used. For example, a retroviral vector can be used (*see*, Miller *et al.*, 1993, Meth. Enzymol. 217: 581-599). These retroviral vectors have been modified to delete retroviral sequences that are not necessary for packaging of the viral genome and integration into host cell DNA. The CLASP-2 nucleic acid to be used in gene therapy is cloned into the vector, which facilitates delivery of the gene into a patient. More detail about retroviral vectors can be found in Boesen *et al.*, 1994, Biotherapy 6: 291-302, which describes the use of a retroviral vector to deliver the *mdr1* gene to hematopoietic stem cells in order to make the stem cells more resistant to chemotherapy. Other references illustrating the use of retroviral vectors in gene therapy are: Clowes *et al.*, 1994, J. Clin. Invest. 93: 644-651; Kiem *et al.*, 1994, Blood 83: 1467-1473; Salmons and Gunzberg, 1993, Human Gene Therapy 4: 129-141; and Grossman and Wilson, 1993, Curr. Opin. in Genetics and Devel. 3: 110-114.

Adenoviruses are other viral vectors that can be used in gene therapy. Adenoviruses are especially attractive vehicles for delivering genes to respiratory epithelia. Adenoviruses naturally infect respiratory epithelia where they cause a mild disease. Other targets for adenovirus-based delivery systems are liver, the central nervous system, endothelial cells, and muscle. Adenoviruses have the advantage of being capable of infecting non-dividing cells. Kozarsky and Wilson 1993, Current Opinion in Genetics and Development 3: 499-503) present a review of adenovirus-based gene therapy. Bout *et al.*, 1994, Human Gene Therapy 5: 3-10, demonstrated the use of adenovirus vectors to transfer genes to the respiratory epithelia of rhesus monkeys. Other instances of the use of adenoviruses in gene therapy can be found in Rosenfeld *et al.*, 1991, Science 252: 431-434; Rosenfeld *et al.*, 1992, Cell 68: 143-155; and Mastrangeli *et al.*, 1993, J. Clin. Invest. 91: 225-234. Adeno-associated virus (AAV) has also been proposed for use in gene therapy (Walsh *et al.*, 1993, Proc. Soc. Exp. Biol. Med. 204: 289-300).

Another approach to gene therapy involves transferring a gene to cells in tissue culture by such methods as electroporation, lipofection, calcium phosphate mediated transfection, or viral infection. Usually, the method of transfer includes the transfer of a

selectable marker to the cells. The cells are then placed under selection to isolate those cells that have taken up and are expressing the transferred gene. Those cells are then delivered to a patient.

In this embodiment, the nucleic acid is introduced into a cell prior to
5 administration *in vivo* of the resulting recombinant cell. Such introduction can be carried out by any method known in the art, including but not limited to transfection, electroporation, microinjection, infection with a viral or bacteriophage vector containing the nucleic acid sequences, cell fusion, chromosome-mediated gene transfer, microcell-mediated gene transfer, spheroplast fusion, and the like. Numerous techniques are known in the art for the
10 introduction of foreign genes into cells (*see, e.g.*, Loeffler and Behr, 1993, Meth. Enzymol. 217: 599-618; Cohen *et al.*, 1993, Meth. Enzymol. 217: 618-644; Cline, 1985, Pharmac. Ther. 29: 69-92) and can be used in accordance with the present invention, provided that the necessary developmental and physiological functions of the recipient cells are not disrupted. The technique should provide for the stable transfer of the nucleic acid to the cell, so that the
15 nucleic acid is expressible by the cell and preferably heritable and expressible by its cell progeny.

The resulting recombinant cells can be delivered to a patient by various methods known in the art. In a preferred embodiment, epithelial cells are injected, *e.g.*, subcutaneously. In another embodiment, recombinant skin cells can be applied as a skin graft
20 onto the patient. Recombinant blood cells (*e.g.*, hematopoietic stem or progenitor cells) are preferably administered intravenously. The amount of cells envisioned for use depends on the desired effect, patient state, and the like., and can be determined by one skilled in the art.

Cells into which a nucleic acid can be introduced for purposes of gene therapy encompass any desired, available cell type, and include but are not limited to epithelial cells,
25 endothelial cells, keratinocytes, fibroblasts, muscle cells, hepatocytes; blood cells such as T lymphocytes, B lymphocytes, monocytes, macrophages, neutrophils, eosinophils, megakaryocytes, granulocytes; various stem or progenitor cells, in particular hematopoietic stem or progenitor cells, *e.g.*, as obtained from bone marrow, umbilical cord blood, peripheral blood, fetal liver, and the like. In a preferred embodiment, the cell used for gene therapy is
30 autologous to the patient.

In a specific embodiment, the nucleic acid to be introduced for purposes of gene therapy comprises an inducible promoter operably linked to the coding region, such that expression of the nucleic acid is controllable by controlling the presence or absence of the appropriate inducer of transcription.

5.4.2.3. Knockout Cells

In one aspect of the invention, endogenous target gene expression can also be reduced by inactivating or “knocking out” the target gene or its promoter using targeted homologous recombination (*see, e.g.,* Smithies *et al.*, 1985, Nature 317: 230-234; Thomas and Capecchi, 1987, Cell 51: 503-512; Thompson *et al.*, 1989, Cell 5: 313-321; each of which is incorporated by reference herein in its entirety). For example, a mutant, non-functional target gene (or a completely unrelated DNA sequence) flanked by DNA homologous to the endogenous target gene (either the coding regions or regulatory regions of the target gene) can be used, with or without a selectable marker and/or a negative selectable marker, to transfect cells that express the target gene *in vivo*. Insertion of the DNA construct, via targeted homologous recombination, results in inactivation of the target gene. Such approaches are particularly suited in the agricultural field where modifications to ES (embryonic stem) cells can be used to generate animal offspring with an inactive target gene (*see, e.g.,* Thomas and Capecchi, 1987 and Thompson, 1989, *supra*). However, this approach can be adapted for use in humans provided the recombinant DNA constructs are directly administered or targeted to the required site *in vivo* using appropriate viral vectors.

5.4.2.4. Transgenic and Knockout Animals

The CLASP-2 gene product can also be expressed in transgenic animals. Animals of any species, including, but not limited to, mice, rats, rabbits, guinea pigs, pigs, micro-pigs, goats, sheep, and non-human primates, *e.g.,* baboons, monkeys, and chimpanzees can be used to generate CLASP-2 transgenic animals. The term “transgenic,” as used herein, refers to animals expressing CLASP-2 gene sequences from a different species (*e.g.,* mice expressing human CLASP-2 gene sequences), as well as animals that have been genetically engineered to overexpress endogenous (*i.e.,* same species) CLASP-2 sequences or animals that have been genetically engineered to no longer express endogenous CLASP-2 gene sequences (*i.e.,* “knock-out” animals), and their progeny.

Any technique known in the art can be used to introduce a CLASP-2 transgene into animals to produce the founder lines of transgenic animals. Such techniques include, but are not limited to pronuclear microinjection (Hoppe and Wagner, 1989, U.S. Pat. No. 4,873,191); retrovirus mediated gene transfer into germ lines (Van der Putten *et al.*, 1985, Proc. Natl. Acad. Sci., U.S.A. 82: 6148-6152); gene targeting in embryonic stem cells (Thompson *et al.*, 1989, Cell 56: 313-321); electroporation of embryos (Lo, 1983, Mol. Cell.

Biol. 3: 1803-1814); and sperm-mediated gene transfer (Lavitrano *et al.*, 1989, Cell 57: 717-723) (For a review of such techniques, see Gordon, 1989, Transgenic Animals, Intl. Rev. Cytol. 115, 171-229)

Any technique known in the art can be used to produce transgenic animal clones containing a CLASP-2 transgene, for example, nuclear transfer into enucleated oocytes of nuclei from cultured embryonic, fetal or adult cells induced to quiescence (Campbell *et al.*, 1996, Nature 380: 64-66; Wilmut *et al.*, Nature 385: 810-813).

The present invention provides for transgenic animals that carry a CLASP-2 transgene in all their cells, as well as animals that carry the transgene in some, but not all their cells, *i.e.*, mosaic animals. The transgene can be integrated as a single transgene or in concatamers, *e.g.*, head-to-head tandems or head-to-tail tandems. The transgene can also be selectively introduced into and activated in a particular cell type by following, for example, the teaching of Lasko *et al.* (1992, Proc. Natl. Acad. Sci. U.S.A. 89: 6232-6236). The regulatory sequences required for such a cell-type specific activation will depend upon the particular cell type of interest, and will be apparent to those of skill in the art. When it is desired that the CLASP-2 transgene be integrated into the chromosomal site of the endogenous CLASP-2 gene, gene targeting is preferred. Briefly, when such a technique is to be utilized, vectors containing some nucleotide sequences homologous to the endogenous CLASP-2 gene are designed for the purpose of integrating, via homologous recombination with chromosomal sequences, into and disrupting the function of the nucleotide sequence of the endogenous CLASP-2 gene. The transgene can also be selectively introduced into a particular cell type, thus inactivating the endogenous CLASP-2 gene in only that cell type, by following, for example, the teaching of Gu *et al.* (1994, Science 265: 103-106). The regulatory sequences required for such a cell-type specific inactivation will depend upon the particular cell type of interest, and will be apparent to those of skill in the art.

Once transgenic animals have been generated, the expression of the recombinant CLASP-2 gene can be assayed utilizing standard techniques. Initial screening can be accomplished by Southern blot analysis or PCR techniques to analyze animal tissues to assay whether integration of the transgene has taken place. The level of mRNA expression of the transgene in the tissues of the transgenic animals can also be assessed using techniques that include, but are not limited to, Northern blot analysis of tissue samples obtained from the animal, *in situ* hybridization analysis, and RT-PCR (reverse transcriptase PCR). Samples of CLASP-2 gene-expressing tissue, can also be evaluated immunocytochemically using antibodies specific for the CLASP-2 transgene product.

5.4.2.5. Other Uses of CLASP Polynucleotides

There exists an ongoing need to identify new chromosome marking reagents. Sequences can be mapped to chromosomes by preparing PCR primers from SEQ ID NO: 1, 3, 5, or 9. These primers can be less than 50 nucleotides in length, generally less than 46 nucleotides, more generally less than 41 nucleotides, most generally less than 36 nucleotides, preferably less than 31 nucleotides, more preferably less than 26 nucleotides, and most preferably less than 21 nucleotides in length. The probes can also be less than 16 nucleotides, less than 13 nucleotides in length, less than 9 nucleotides in length and less than 7 nucleotides in length. Primers can be selected so that the primers do not span more than one predicted exon in the genomic DNA. These primers are then used for PCR screening of somatic cell hybrids containing individual human chromosomes (*i.e.*, chromosome 13). Only those hybrids containing the human CLASP-2 gene corresponding to SEQ ID NO: 1, 3, 5, or 9 will yield an amplified fragment.

Similarly, somatic hybrids provide a rapid method of PCR mapping the polynucleotides to particular chromosomes. Precise chromosomal location of the CLASP-2 polynucleotides can also be achieved using fluorescence in situ hybridization (FISH) of a metaphase chromosomal spread. See Verma, et al, Human Chromosomes: A Manual of Basic Techniques, Pergamon Press. NY, 1988. Once a polynucleotide has been mapped to a precise chromosomal location, the physical position of the polynucleotide can be used in linkage analysis. Linkage analysis establishes coinheritance between a chromosomal location and presentation of a particular disease. See McKusick, V., 1998, Mendelian Inheritance in Man : A Catalog of Human Genes and Genetic Disorders, 12th Ed, Johns Hopkins University Press.

The CLASP-2 polynucleotides can be used for identifying individuals from minute biological samples as DNA markers for restriction fragment length polymorphism (RFLP). An individual's genomic DNA is digested with one or more restriction enzymes, and probed on a Southern blot with CLASP-2 DNA markers to yield unique bands for identifying the individual.

As described above, upon sequencing of numerous independent cDNA products, single nucleotide polymorphisms (SNPs) have been discovered within CLASP-2. These alterations and differences are presented in FIG 11B. They represent mis-sense alterations.

If it is determined that certain SNPs are deleterious or advantageous, SNPs can be used as a diagnostic tool through SNP mapping or direct sequencing of the SNP region to determine which isoform is expressed. Additionally, the SNPs can be used as a general SNP marker for chromosomal defects such as rearrangement and translocations.

5 CLASP-2 polynucleotides can be also be used as polymorphic markers for forensic analysis. See generally National Research Council, *The Evaluation of Forensic DNA Evidence* (Eds. 1996, Pollard *et al.*, National Academy Press, Washington D.C.). The capacity to identify a distinguishing or unique set of forensic markers in an individual is useful for forensic analysis. For example, one can determine whether a blood sample from a
10 suspect matches a blood or other tissue sample from a crime scene by determining whether the set of polymorphic forms occupying selected polymorphic sites is the same in the suspect and the sample. If the set of polymorphic markers does not match between a suspect and a sample, it can be concluded (barring experimental error) that the suspect was not the source of the sample. If the set of markers does match, one can conclude that the DNA from the
15 suspect is consistent with that found at the crime scene. If frequencies of the polymorphic forms at the loci tested have been determined (*e.g.*, by analysis of a suitable population of individuals), one can perform a statistical analysis to determine the probability that a match of suspect and crime scene sample would occur by chance.

To make such an identification, PCR technology can be used to amplify DNA
20 sequences taken from very small biological samples such as tissues, *e.g.*, hair or skin, or body fluids, *e.g.*, blood, saliva, or semen found at a crime scene. The amplified sequence can then be compared to a standard, thereby allowing identification of the origin of the biological sample. The CLASP-2 polynucleotide sequences of the present invention can be used to provide polynucleotide reagents, *e.g.*, PCR primers, targeted to specific loci in the human
25 genome, which can enhance the reliability of DNA-based forensic identifications by, for example, providing another “identification marker” (*i.e.* another DNA sequence that is unique to a particular individual). As mentioned above, actual base sequence information can be used for identification as an accurate alternative to patterns formed by restriction enzyme generated fragments. Sequences targeted to noncoding regions of SEQ ID NO: 1, 3, 5 or 9 are
30 particularly appropriate for this use as greater numbers of polymorphisms occur in the noncoding regions, making it easier to differentiate individuals using this technique. Examples of polynucleotide reagents include the CLASP-2 nucleotide sequences or portions thereof, *e.g.*, fragments derived from the noncoding regions of SEQ ID NO: 1, 3, 5, or 9

having a length of at least 20 bases, preferably at least 25 bases, and more preferably at least 30 bases.

CLASP-2 polynucleotides can also be used as reagents for paternity testing.

The object of paternity testing is usually to determine whether a male is the father of a child.

5 In most cases, the mother of the child is known and thus, the mother's contribution to the child's genotype can be traced. Paternity testing investigates whether the part of the child's genotype not attributable to the mother is consistent with that of the putative father. Paternity testing can be performed by analyzing sets of polymorphisms in the putative father and the child. Of course, the present invention can be expanded to the use of this procedure to
10 determine if one individual is related to another. Even more broadly, the present invention can be employed to determine how related one individual is to another, for example, between races or species.

Bacterial infections are a major cause of health-related problems. However, the emergence of drug resistant bacteria is compromising the therapeutic value of the present
15 spectrum of antibiotics. All the currently used antibiotics are small organic molecules, with certain level of structural similarity. This provides an advantage for bacteria to develop drug resistance, since they need to modify a limited number of genes in order to become resistant to a wide variety of antibiotics. The development of antibiotics with different chemical structure and targets can overcome antibiotic resistance, and provide therapeutic superiority
20 in preventing infection by bacterial pathogens. Additionally, most antibiotics are not naturally occurring compounds and cause minor or sometimes serious side effects. For example, antibiotics used to treat TB can cause hearing loss.

The present invention provides new antibacterial agents. Certain CLASP-2 DNA sequences were difficult to clone and subclone (*see* Example 1). Bacteria harboring
25 certain pieces of CLASP cDNA products were unable to be isolated, indicating that introduction of CLASP sequences compromised bacterial viability. There can be at least two possible reasons why the CLASP cDNA were unable to be cloned, which can reflect a variation of the well-established Modification and Restriction systems found in bacteria (reviewed in Wilson and Murray. (1991) *Annu. Rev. Genet.* 25:585-627; Bickle and Kruger (1993) *Microbiol. Rev.* 57:29-67). This well-described system is used by bacteria to prevent
30 deleterious effects caused by the introduction of foreign DNA. Bacteria can recognize foreign DNA since it does not have the same modifications (e.g. methylation) as the native DNA. After recognition, the bacteria then digest and eliminate the foreign DNA (restriction). In the first scenario, the CLASP cDNA can be recognized as foreign DNA, and digested and

eliminated as in the Modification and Restriction system. However, this would be unique for CLASP cDNA since the bacteria used for cloning cDNA are compromised in the Modification and Restriction system, which makes cloning of cDNA into bacteria a practice common in the art. If this is the case, the bacterial apparatus that specifically recognizes or eliminates CLASP cDNA can provide a novel target to develop antimicrobial agents. The CLASP DNA sequence would be useful in targeting the apparatus as well as an entry point for designing screens to identify potential targets. The second possibility is that CLASP cDNA behaves as an antimicrobial agent (i.e., antibiotic), and prevents bacterial growth. This, in effect, would create a new type of antibiotic mediated by the presence of foreign DNA (i.e. CLASP cDNA). In the case for the CLASP cDNA, the bacteria can recognize the DNA but instead of digesting and eliminating the DNA, the CLASP cDNA can cause a variation of the restriction and prevent the bacteria from growing, imposing a bacteriotoxic effect upon the bacteria.

DNA as an antimicrobial agent has significant advantages over currently available agents. First, it is structurally unrelated to any existing antibiotics, and can overcome the present growing drug-resistance problem to structurally common agents. Second, since DNA antimicrobials composed of naturally-occurring human DNA, are expected to have minimal side effects and immune rejection. Third, DNA sequences can be tailored with sequence variation and numerous chemical modifications to circumvent the problem of resistance. Fourth, the antimicrobial DNA can be delivered specifically to bacterial cells through the use of bacteriophages (i.e., bacterial virus) which specifically infect bacteria and do not infect human cells. Further specificity can be generated to infect certain bacteria and bacterial subpopulations. Finally, this system can be economically robust since the generation of DNA and delivery vehicles are inexpensive.

5.5. Polypeptides Encoded by the CLASP Gene Coding Sequence

In accordance with the invention, a CLASP polynucleotide which encodes the CLASP polypeptides, mutant polypeptides, peptide fragments, CLASP fusion proteins or functional equivalents thereof, can be used to express CLASP proteins in appropriate host cells. In various embodiments, the CLASP-2 polypeptides expressed will be identical or substantially similar to SEQ ID NOs: 2, 4, 6 or 10 or a fragment thereof.

In some embodiments, altered DNA sequences which can be used in accordance with the invention include deletions, additions or substitutions of different nucleotide residues resulting in a sequence that encodes the same or a functionally equivalent

gene product. For example, due to the inherent degeneracy of the genetic code, other DNA sequences which encode substantially the same or a functionally equivalent amino acid sequence, can be used in the practice of the invention for the expression of the CLASP protein. Because of the degeneracy of the genetic code, a large number of functionally identical nucleic acids encode any given protein. For instance, the codons GCA, GCC, GCG and GCU all encode the amino acid alanine. Thus, at every position where an alanine is specified by a codon, the codon can be altered to any of the corresponding codons described without altering the encoded polypeptide. Such nucleic acid variations are "silent variations," which are one species of conservatively modified variations. One of skill will recognize that each codon in a nucleic acid sequence such SEQ ID NO: 1 (except AUG, which is ordinarily the only codon for methionine, and TGG, which is ordinarily the only codon for tryptophan) can be modified to yield a functionally identical molecule. Accordingly, each silent variation of a nucleic acid which encodes a polypeptide is implicit in each described sequence. Thus, for example, due to the degeneracy of the genetic code, a polypeptide having the sequence of SEQ ID NO: 2 or a fragment thereof, can be encoded by numerous polynucleotides other than SEQ ID NO: 1. Typically, the degenerate sequence will hybridize with SEQ ID NO: 1 under high or moderate stringency conditions, but this is not strictly required (*e.g.*, when a copy of a nucleic acid is created using the maximum codon degeneracy permitted by the genetic code. In such cases, the nucleic acids typically hybridize under moderately stringent hybridization conditions.)

The gene product itself can contain deletions, additions or substitutions of amino acid residues within a CLASP sequence, which result in a silent change thus producing a functionally equivalent CLASP protein. Such conservative amino acid substitutions can be made on the basis of similarity in polarity, charge, solubility, hydrophobicity, hydrophilicity, and/or the amphipathic nature of the residues involved. For example, negatively charged amino acids include aspartic acid and glutamic acid; positively charged amino acids include lysine, histidine and arginine; amino acids with uncharged polar head groups having similar hydrophilicity values include the following: glycine, asparagine, glutamine, serine, threonine, tyrosine; and amino acids with nonpolar head groups include alanine, valine, isoleucine, leucine, phenylalanine, proline, methionine, tryptophan. Creighton, 1984, *PROTEINS*, has grouped amino acids that are conservative substitutions for one another as follows: (1) Alanine (A), Glycine (G); (2) Aspartic acid (D), Glutamic acid (E); (3) Asparagine (N), Glutamine (Q); (4) Arginine (R), Lysine (K); (5) Isoleucine (I), Leucine (L), Methionine (M),

Valine (V); (6) Phenylalanine (F), Tyrosine (Y), Tryptophan (W); (7) Serine (S), Threonine (T); and (8) Cysteine (C), Methionine (M).

The DNA sequences of the invention can be engineered in order to alter a CLASP coding sequence for a variety of ends, including but not limited to, alterations which
5 modify processing and expression of the gene product. For example, mutations can be introduced using techniques which are well known in the art, *e.g.*, site-directed mutagenesis, to insert new restriction sites, to alter glycosylation patterns, phosphorylation, and the like. Based on the domain organization of the CLASP proteins, a large number of CLASP mutant polypeptides can be constructed by modifying or rearranging the nucleotide sequences that
10 encode the CLASP extracellular, transmembrane and cytoplasmic domains.

In various embodiments, the present invention provides homologues of the CLASP polypeptides which function as either an CLASP agonists or an CLASP-2 antagonist. In a preferred embodiment, the CLASP agonists and antagonists stimulate or inhibit, respectively, a subset of the biological activities of the naturally occurring form of the
15 CLASP-2 polypeptide. Thus, specific biological effects can be elicited by treatment with a homologue of limited function. In one embodiment, treatment of a subject with a homologue having a subset of the biological activities of the naturally occurring form of the polypeptide has fewer side effects in a subject relative to treatment with the naturally occurring form of the CLASP-2 polypeptide.

20 The invention contemplates both full-length CLASP polypeptides and fragments, *e.g.*, fragments having a length of at least about 10, often 20, frequently 50 or 100 residues substantially identical to the exemplified CLASP polypeptide sequences of the invention. Protein fragments can be “free-standing,” or comprised within a larger polypeptide of which the fragment forms a part or region, most preferably as a single
25 continuous region. Representative examples of polypeptide fragments of the invention, include, for example, fragments from about amino acid number 1-20, 2 1-40, 4 1-60, 61-80, 81-100, 102-120, 121-140, 141-160, 161-180, 181-200, or 201 to the end of the coding region. Moreover, polypeptide fragments can be about 20, 30, 40, 50, 60, 70, 80, 90, 100, 110, 120, 130, 140, 150, 200 amino acids in length. In this context “about” includes the
30 particularly recited ranges, larger or smaller by several (5, 4, 3, 2, or 1) amino acids, at either extreme or at both extremes.

Preferred polypeptide fragments include the CLASP protein. Further preferred polypeptide fragments include the CLASP-2 protein having a continuous series of deleted residues from the amino or the carboxy terminus, or both. For example, any number of amino

acids, ranging from 1-X, can be deleted from the amino terminus of either the CLASP-2 polypeptide. Furthermore, any combination of the above amino and carboxy terminus deletions are preferred. Similarly, polynucleotide fragments encoding these CLASP-2 polypeptide fragments are also preferred.

5 Even if deletion of one or more amino acids from the N-terminus of a protein results in modification or loss of one or more biological functions of the protein, other biological activities can still be retained. Thus, the ability of shortened CLASP muteins to induce and/or bind to antibodies which recognize the complete or mature forms of the polypeptides generally will be retained when less than the majority of the residues of the
10 complete or mature polypeptide are removed from the N-terminus. Whether a particular polypeptide lacking N-terminal residues of a complete polypeptide retains such immunologic activities can readily be determined by routine methods described herein and otherwise known in the art. It is not unlikely that a CLASP-2 mutein with a large number of deleted N-terminal amino acid residues can retain some biological or immunogenic activities. In fact,
15 peptides composed of as few as four CLASP-2 amino acid residues can often evoke an immune response.

 Homologues of the CLASP-2 polypeptide can be generated by mutagenesis, *e.g.*, discrete point mutation or truncation of the CLASP-2 polypeptide. As used herein, the term “homologue” refers to a variant form of the CLASP-2 polypeptide which acts as an
20 agonist or antagonist of the activity of the CLASP-2 polypeptide. An agonist of the CLASP-2 polypeptide can retain substantially the same, or a subset, of the biological activities of the CLASP-2 polypeptide. An antagonist of the CLASP-2 polypeptide can inhibit one or more of the activities of the naturally occurring form of the CLASP-2 polypeptide, by, for example, competitively binding to a downstream or upstream member of the CLASP-2 molecular
25 pathway which includes the CLASP-2 polypeptide.

 Modulation can be assayed by determining any parameter that is indirectly or directly affected by the expression of the target gene. Such parameters include, *e.g.*, changes in RNA or protein levels, changes in protein activity, changes in product levels, changes in downstream gene expression, changes in reporter gene transcription (luciferase, CAT, β -galactosidase, β -glucuronidase, GFP (*see, e.g.*, Mistili & Spector, 1997, Nature
30 Biotechnology 15: 961-964); changes in signal transduction, phosphorylation and dephosphorylation, receptor-ligand interactions, second messenger concentrations (*e.g.*, cGMP, cAMP, IP₃, and Ca²⁺), and cell growth. These assays can be *in vitro*, *in vivo*, and *ex vivo*. Such functional effects can be measured by any means known to those skilled in the

art, *e.g.*, measurement of RNA or protein levels, measurement of RNA stability, identification of downstream or reporter gene expression, *e.g.*, via chemiluminescence, fluorescence, colorimetric reactions, antibody binding, inducible markers, ligand binding assays; changes in intracellular second messengers such as cGMP and inositol triphosphate (IP₃); changes in intracellular calcium levels; cytokine release, and the like.

5.5.1. Synthesis or Expression of CLASP-2 Polypeptide Expression Systems

In order to express a biologically active CLASP, the nucleotide sequence coding for CLASP, or a functional equivalent, is inserted into an appropriate expression vector. The CLASP gene product as well as host cells or cell lines transfected or transformed with recombinant CLASP expression vectors can be used for a variety of purposes. These include, but are not limited to, generating antibodies (*i.e.*, monoclonal or polyclonal) that competitively inhibit activity of CLASP protein and neutralize its activity; antibodies that activate CLASP function and antibodies that detect its presence on the cell surface or in solution. Anti-CLASP antibodies can be used in detecting and quantifying expression of CLASP levels in cells and tissues such as lymphocytes and macrophages, as well as isolating CLASP-positive cells from a cell mixture.

Methods which are well known to those skilled in the art can be used to construct recombinant expression vectors containing the CLASP-2 coding sequence and appropriate transcriptional/translational control signals. These methods include *in vitro* recombinant DNA techniques, synthetic techniques and *in vivo* recombination/genetic recombination. (See, *e.g.*, the techniques described in Sambrook *et al.*, 1989, Molecular Cloning A Laboratory Manual, Cold Spring Harbor Laboratory, N.Y. and Ausubel *et al.*, *supra*). The recombinant expression vectors of the invention comprise a nucleic acid of the invention in a form suitable for expression of the nucleic acid in a host cell, which means that the recombinant expression vectors include one or more regulatory sequences, selected on the basis of the host cells to be used for expression, which is operatively linked to the nucleic acid sequence to be expressed. It will be appreciated by those skilled in the art that the design of the expression vector can depend on such factors as the choice of the host cell to be transformed, the level of expression of polypeptide desired, and the like. The expression vectors of the invention can be introduced into host cells to thereby produce polypeptides or peptides, including fusion polypeptides or peptides, encoded by nucleic acids as described herein (*e.g.*, CLASP-2 polypeptides, mutant forms of CLASP-2, fusion polypeptides, and the like).

A variety of host-expression vector systems can be utilized to express a CLASP-2 coding sequence. These include, but are not limited to, microorganisms such as bacteria transformed with recombinant bacteriophage DNA, plasmid DNA, or cosmid DNA expression vectors containing the CLASP-2 coding sequence; yeast transformed with
5 recombinant yeast expression vectors containing the CLASP-2 coding sequence; insect cell systems infected with recombinant virus expression vectors (*e.g.*, baculovirus) containing the CLASP-2 coding sequence; plant cell systems infected with recombinant virus expression vectors (*e.g.*, cauliflower mosaic virus, CaMV; tobacco mosaic virus, TMV) or transformed with recombinant plasmid expression vectors (*e.g.*, Ti plasmid) containing the CLASP-2
10 coding sequence; or animal cell systems. The expression elements of these systems vary in their strength and specificities. Depending on the host/vector system utilized, any of a number of suitable transcription and translation elements, including constitutive and inducible promoters, can be used in the expression vector. For example, when cloning in bacterial systems, inducible promoters such as pL of bacteriophage λ , plac, ptrp, ptac (ptrp-
15 lac hybrid promoter; cytomegalovirus promoter) and the like can be used; when cloning in insect cell systems, promoters such as the baculovirus polyhedron promoter can be used; when cloning in plant cell systems, promoters derived from the genome of plant cells (*e.g.*, heat shock promoters; the promoter for the small subunit of RUBISCO; the promoter for the chlorophyll α/β binding protein) or from plant viruses (*e.g.*, the ³⁵S RNA promoter of CaMV;
20 the coat protein promoter of TMV) can be used; when cloning in mammalian cell systems, promoters derived from the genome of mammalian cells (*e.g.*, metallothionein promoter) or from mammalian viruses (*e.g.*, the adenovirus late promoter; the vaccinia virus 7.5K promoter) can be used; when generating cell lines that contain multiple copies of the CLASP-2 DNA, SV40-, BPV- and EBV-based vectors can be used with an appropriate selectable
25 marker.

In bacterial systems a number of expression vectors can be advantageously selected depending upon the use intended for the expressed CLASP-2 product. For example, when large quantities of CLASP-2 protein are to be produced for the generation of antibodies or to screen peptide libraries, vectors which direct the expression of high levels of fusion
30 protein products that are readily purified can be desirable. Such vectors include, but are not limited to, the *E. coli* expression vector pUR278 (Ruther *et al.*, 1983, EMBO J. 2: 1791), in which the CLASP-2 coding sequence can be ligated into the vector in frame with the lacZ coding region so that a hybrid protein is produced; pIN vectors (Inouye & Inouye, 1985,

Nucleic acids Res. 13: 3101-3109; Van Heeke & Schuster, 1989, J. Biol. Chem. 264: 5503-5509); and the like. pGEX vectors may also be used to express foreign polypeptides as fusion proteins with glutathione S-transferase (GST). In general, such fusion proteins are soluble and can easily be purified from lysed cells by adsorption to glutathione-agarose beads followed by elution in the presence of free glutathione. Proteins made in such systems may be designed to include heparin, thrombin, or factor XA protease cleavage sites so that the cloned polypeptide of interest can be released from the GST moiety at will.

In yeast, a number of vectors containing constitutive or inducible promoters can be used. (Current Protocols in Molecular Biology, Vol. 2, 1988 (Suppl. 1999), Ed. Ausubel *et al.*, Greene Publish. Assoc. & Wiley Interscience, Ch. 13; Grant *et al.*, 1987, Expression and Secretion Vectors for Yeast, in Methods in Enzymology, Eds. Wu & Grossman, 1987, Acad. Press, N.Y., Vol. 153, pp. 516-544; Glover, 1986, DNA Cloning, Vol. II, IRL Press, Wash., D.C., Ch. 3; and Bitter, 1987, Heterologous Gene Expression in Yeast, Methods in Enzymology, Eds. Berger & Kimmel, Acad. Press, N.Y., Vol. 152, pp. 673-684; and The Molecular Biology of the Yeast *Saccharomyces*, 1982, Eds. Strathern *et al.*, Cold Spring Harbor Press, Vols. I and II.)

In cases where plant expression vectors are used, the expression of the CLASP-2 coding sequence can be driven by any of a number of promoters. For example, viral promoters such as the 35S RNA and 19S RNA promoters of CaMV (Brisson *et al.*, 1984, Nature 310: 511-514), or the coat protein promoter of TMV (Takamatsu *et al.*, 1987, EMBO J. 6: 307-311) can be used; alternatively, plant promoters such as the small subunit of RUBISCO (Coruzzi *et al.*, 1984, EMBO J. 3: 1671-1680; Broglie *et al.*, 1984, Science 224: 838-843); or heat shock promoters, *e.g.*, soybean hsp17.5-E or hsp17.3-B (Gurley *et al.*, 1986, Mol. Cell. Biol. 6: 559-565) can be used. These constructs can be introduced into plant cells using Ti plasmids, Ri plasmids, plant virus vectors, direct DNA transformation, microinjection, electroporation, and the like. (Weissbach & Weissbach, 1988, Methods for Plant Molecular Biology, Academic Press, NY, Section VIII, pp. 421-463; and Grierson & Corey, 1988, Plant Molecular Biology, 2d Ed., Blackie, London, Ch. 7-9.)

An alternative expression system which could be used to express CLASP-2 is an insect system. In one such system, *Autographa californica* nuclear polyhedrosis virus (AcNPV) is used as a vector to express foreign genes. The virus grows in *Spodoptera frugiperda* cells. The CLASP-2 coding sequence can be cloned into non-essential regions (*e.g.*, the polyhedron gene) of the virus and placed under control of an AcNPV promoter (*e.g.*, the polyhedron promoter). Successful insertion of the CLASP-2 coding sequence will

result in inactivation of the polyhedron gene and production of non-occluded recombinant virus (*i.e.*, virus lacking the proteinaceous coat coded for by the polyhedron gene). These recombinant viruses are then used to infect *Spodoptera frugiperda* cells in which the inserted gene is expressed. (*see, e.g.*, Smith *et al.*, 1983, J. Virol. 46: 584; Smith, U.S. Patent No. 4,215,051).

In mammalian host cells, a number of viral based expression systems can be utilized. In cases where an adenovirus is used as an expression vector, the CLASP-2 coding sequence can be ligated to an adenovirus transcription/translation control complex, *e.g.*, the late promoter and tripartite leader sequence. This chimeric gene can then be inserted in the adenovirus genome by *in vitro* or *in vivo* recombination. Insertion in a non-essential region of the viral genome (*e.g.*, region E1 or E3) will result in a recombinant virus that is viable and capable of expressing CLASP-2 in infected hosts. (*See, e.g.*, Logan & Shenk, 1984, Proc. Natl. Acad. Sci. U.S.A. 81: 3655-3659). Alternatively, the vaccinia 7.5K promoter can be used. (*See, e.g.*, Mackett *et al.*, 1982, Proc. Natl. Acad. Sci. U.S.A. 79: 7415-7419; Mackett *et al.*, 1984, J. Virol. 49: 857-864; Panicali *et al.*, 1982, Proc. Natl. Acad. Sci. U.S.A. 79: 4927-4931). Regulatable expression vectors such as the tetracycline repressible vectors can also be used to express a coding sequence in a controlled fashion.

Specific initiation signals can also be required for efficient translation of inserted CLASP-2 coding sequences. These signals include the ATG initiation codon and adjacent sequences. In cases where the entire CLASP-2 gene, including its own initiation codon and adjacent sequences, is inserted into the appropriate expression vector, no additional translational control signals can be needed. However, in cases where only a portion of the CLASP-2 coding sequence is inserted, exogenous translational control signals, including the ATG initiation codon, must be provided. Furthermore, the initiation codon must be in phase with the reading frame of the CLASP-2 coding sequence to ensure translation of the entire insert. These exogenous translational control signals and initiation codons can be of a variety of origins, both natural and synthetic. The efficiency of expression can be enhanced by the inclusion of appropriate transcription enhancer elements, transcription terminators, and the like. (*see* Bittner *et al.*, 1987, Methods in Enzymol. 153: 516-544).

In addition, a host cell strain can be chosen which modulates the expression of the inserted sequences, or modifies and processes the gene product in a specific fashion desired. Such modifications (*e.g.*, glycosylation) and processing (*e.g.*, cleavage) of protein products can be important for the function of the protein. The presence of several consensus

N-glycosylation sites in CLASP-2 extracellular domains support the possibility that proper modification can play a role in CLASP-2 function. Different host cells have characteristic and specific mechanisms for the post-translational processing and modification of proteins. Appropriate cell lines or host systems can be chosen to ensure the correct modification and processing of the foreign protein expressed. To this end, eukaryotic host cells which possess the cellular machinery for proper processing of the primary transcript, glycosylation, and phosphorylation of the gene product can be used. Such mammalian host cells include, but are not limited to, CHO, VERO, BHK, HeLa, COS, MDCK, 293, WI38, and the like.

Host cells transformed with nucleotide sequences encoding CLASP-2 may be cultured under conditions suitable for the expression and recovery of the soluble protein from cell culture. The protein produced by a transformed cell may be secreted or contained intracellularly depending on the sequence and/or the vector used. As will be understood by those of skill in the art, expression vectors containing polynucleotides which encode CLASP-2 may be designed to contain signal sequences which direct secretion of CLASP-2 through a prokaryotic or eukaryotic cell membrane. Other constructions may be used to join sequences encoding CLASP-2 to nucleotide sequence encoding a polypeptide domain which will facilitate purification of soluble proteins. Such purification facilitating domains include, but are not limited to, metal chelating peptides such as histidine-tryptophan modules that allow purification on immobilized metals, protein A domains that allow purification on immobilized immunoglobulin,

For long-term, high-yield production of recombinant proteins, stable expression is preferred. For example, cell lines which stably express CLASP-2 proteins can be engineered. Rather than using expression vectors which contain viral origins of replication, host cells can be transformed with the CLASP-2 DNA controlled by appropriate expression control elements (*e.g.*, promoter, enhancer, sequences, transcription terminators, polyadenylation sites, and the like.), and a selectable marker. Following the introduction of foreign DNA, engineered cells can be allowed to grow for 1-2 days in an enriched medium, and then switched to a selective medium. The selectable marker in the recombinant plasmid confers resistance to the selection and allows cells to stably integrate the plasmid into their chromosomes and grow to form foci which in turn can be cloned and expanded into cell lines. This method can advantageously be used to engineer cell lines which express the CLASP-2 protein(s) on the cell surface. Such engineered cell lines are particularly useful in screening for molecules or drugs that affect CLASP-2 function.

A number of selection systems can be used, including but not limited to, the herpes simplex virus thymidine kinase (Wigler *et al.*, 1977, Cell 11: 223), hypoxanthine-guanine phosphoribosyltransferase (Szybalska & Szybalski, 1962, Proc. Natl. Acad. Sci. U.S.A. 48: 2026), and adenine phosphoribosyltransferase (Lowy *et al.*, 1980, Cell 22: 817) genes which can be employed in *tk⁻*, *hgp^r* or *ap^r* cells, respectively. Also, antimetabolite resistance can be used as the basis of selection for *dhfr*, which confers resistance to methotrexate (Wigler *et al.*, 1980, Natl. Acad. Sci. U.S.A. 77: 3567; O'Hare *et al.*, 1981, Proc. Natl. Acad. Sci. U.S.A. 78: 1527); *gpt*, which confers resistance to mycophenolic acid (Mulligan & Berg, 1981), Proc. Natl. Acad. Sci. U.S.A. 78: 2072); *neo*, which confers resistance to the aminoglycoside G-418 (Colberre-Garapin *et al.*, 1981, J. Mol. Biol. 150: 1); and *hygro*, which confers resistance to hygromycin (Santerre *et al.*, 1984, Gene 30: 147). Additional selectable genes have been described, namely *trpB*, which allows cells to utilize indole in place of tryptophan; *hisD*, which allows cells to utilize histinol in place of histidine (Hartman & Mulligan, 1988, Proc. Natl. Acad. Sci. U.S.A. 85: 8047); *ODC* (ornithine decarboxylase) which confers resistance to the ornithine decarboxylase inhibitor, 2-(difluoromethyl)-DL-ornithine, DFMO (McConlogue L., 1987, In: Current Communications in Molecular Biology, Cold Spring Harbor Laboratory ed.) and glutamine synthetase (Bebbington *et al.*, 1992, Biotech 10: 169).

In an alternate embodiment of the invention, the coding sequence of CLASP-2 could be synthesized in whole or in part, using chemical methods well known in the art. (See, *e.g.*, Caruthers *et al.*, 1980, Nuc. Acids Res. Symp. Ser. 7: 215-233; Crea and Horn, 180, Nuc. Acids Res. 9(10): 2331; Matteucci and Caruthers, 1980, Tetrahedron Letter 21: 719; and Chow and Kempe, 1981, Nuc. Acids Res. 9(12): 2807-2817.) Alternatively, the protein itself could be produced using chemical methods to synthesize a CLASP-2 amino acid sequence in whole or in part. For example, peptides can be synthesized by solid phase techniques, cleaved from the resin, and purified by preparative high performance liquid chromatography. (See Creighton, 1983, Proteins Structures And Molecular Principles, W.H. Freeman and Co., N.Y. pp. 50-60). The composition of the synthetic polypeptides can be confirmed by amino acid analysis or sequencing (*e.g.*, the Edman degradation procedure; see Creighton, 1983, Proteins, Structures and Molecular Principles, W.H. Freeman and Co., N.Y., pp. 34-49).

In some embodiments, the CLASP-2 polypeptide contains non-naturally occurring amino acids or amino acid analogs (*i.e.*, compounds that have the same basic chemical structure as a naturally occurring amino acid, *i.e.*, an α carbon that is bound to a

hydrogen, a carboxyl group, an amino group, and an R group, *e.g.*, homoserine, norleucine, methionine sulfoxide, methionine methyl sulfonium).

5.5.2. Identification of Cells That Express CLASP

The recombinant host cells which contain the coding sequence and which
5 express a CLASP gene product or fragments thereof can be identified by at least four general
approaches; (a) DNA-DNA or DNA-RNA hybridization; (b) the presence or absence of
“marker” gene functions; (c) assessing the level of transcription as measured by the
expression of CLASP-2 mRNA transcripts in the host cell; and (d) detection of the gene
product as measured by immunoassay or by its biological activity. Prior to the identification
10 of gene expression, the host cells can be first mutagenized in an effort to increase the level of
expression of CLASP, especially in cell lines that produce low amounts of CLASP.

In the first approach, the presence of the CLASP-2 coding sequence inserted
in the expression vector can be detected by DNA-DNA or DNA-RNA hybridization using
probes comprising nucleotide sequences that are homologous to the CLASP-2 coding
15 sequence, respectively, or portions or derivatives thereof.

In the second approach, the recombinant expression vector/host system can be
identified and selected based upon the presence or absence of certain “marker” gene
functions (*e.g.*, thymidine kinase activity, resistance to antibiotics, resistance to methotrexate,
transformation phenotype, occlusion body formation in baculovirus, and the like). For
20 example, if the CLASP-2 coding sequence is inserted within a marker gene sequence of the
vector, recombinants containing the CLASP-2 coding sequence can be identified by the
absence of the marker gene function. Alternatively, a marker gene can be placed in tandem
with the CLASP-2 sequence under the control of the same or different promoter used to
control the expression of the CLASP-2 coding sequence. Expression of the marker in
25 response to induction or selection indicates expression of the CLASP-2 coding sequence.

In the third approach, transcriptional activity for the CLASP-2 coding region
can be assessed by hybridization assays. For example, RNA can be isolated and analyzed by
Northern blot using a probe homologous to the CLASP-2 coding sequence or particular
portions thereof. Alternatively, total nucleic acids of the host cell can be extracted and
30 assayed for hybridization to such probes. Additionally, reverse transcription-polymerase
chain reactions can be used to detect low levels of gene expression.

In the fourth approach, the expression of the CLASP-2 protein product can be
assessed immunologically, for example by Western blots, immunoassays such as

radioimmuno-precipitation, enzyme-linked immunoassays, fluorescent activated cell sorting (“FACS”), and the like. This can be achieved by using an anti-CLASP-2 antibody.

Alternatively, CLASP-2 protein can be expressed as a fusion protein with green-fluorescent protein to facilitate its detection in cells (United States Patent Nos. 5,491,084; 5,804,387;

5 5,777,079).

Identification of cells or tissues expressing CLASP protein or mRNA, especially CLASP-2 isoforms, can be useful for determining normal and abnormal CLASP expression in a given cell or tissue. As discussed above, a number of CLASP-2 isoforms have been identified, *e.g.*, in Jurkat cells, peripheral blood, and brain. The identification of
10 mRNA or protein expression in various cell types and tissues can allow for identification of isoforms improperly expressed in either a spatial or temporal manner. Expression of hCLASP-2D isoform in hematopoietic cells may cause problems due to the presence of the SH3 domain not seen in the Jurkat and peripheral blood isoforms.

Other molecules in the immune system may also interact with portions of
15 hCLASP2D. However, the absence of the PBM domain in the hCLASP-2D isoform may be necessary for function in certain cell types or tissues. Similarly, expression of CLASP isoforms 2A, 2B, and 2C in brain may cause problems for different reasons: the PBM present in these isoforms may interfere with a particular function by binding any of the known PDZ domain protein involved in formation of the neurological synapse. Similarly, the lack of an
20 SH3 domain may cause an inappropriate response due to interactions with only a subset of molecules required for CLASP-2 function in the brain.

5.5.3. Uses of CLASP-2 Engineered Host Cells

In one embodiment of the invention, the CLASP-2 protein and/or cell lines that express CLASP-2 can be used to screen for antibodies, peptides, small molecules, natural
25 and synthetic compounds or other cell bound or soluble molecules that bind to the CLASP-2 protein resulting in stimulation or inhibition of CLASP-2 function. For example, anti-CLASP-2 antibodies can be used to inhibit or stimulate CLASP-2 function and to detect its presence. Alternatively, screening of peptide libraries with recombinantly expressed soluble CLASP-2 protein or cell lines expressing CLASP-2 protein can be useful for identification of
30 therapeutic molecules that function by inhibiting or stimulating the biological activity of CLASP-2. The uses of the CLASP-2 protein and engineered cell lines, described in the subsections below, can be employed equally well for homologous CLASP-2 genes in various species.

In a specific embodiment of the invention, cell lines may be engineered to express the extracellular or intracellular domain of CLASP fused to another molecule such as GST. In addition, CLASP, its extracellular domain or its intracellular domain may be fused to an immunoglobulin constant region (Hollenbaugh and Aruffo, 1992, Current Protocols in Immunology, Unit 10.19; Aruffo *et al.*, 1990, Cell 61: 1303) to produce a soluble molecule with increased half life. The soluble protein or fusion protein can be used in binding assays, affinity chromatography, immunoprecipitation, Western blot, and the like. Synthetic compounds, natural products, and other sources of potentially biologically active materials can be screened in assays that are well known in the art.

Random peptide libraries consisting of all possible combinations of amino acids attached to a solid phase support can be used to identify peptides that are able to bind to a specific domain of CLASP-2 (Lam, K.S. *et al.*, 1991, Nature 354: 82-84). The screening of peptide libraries can have therapeutic value in the discovery of pharmaceutical agents that stimulate or inhibit the biological activity of CLASP-2.

Identification of molecules that are able to bind to the CLASP-2 protein can be accomplished by screening a peptide library with recombinant soluble CLASP-2 protein. Methods for expression and purification of CLASP-2 are described in Section 5.7, *supra*, and can be used to express recombinant full length CLASP-2 or fragments of CLASP-2 depending on the functional domains of interest. Such domains include CLASP-2 extracellular domain, transmembrane domain, CLASP-2 intracellular domain, ITAM containing domain, tyrosine phosphorylation site containing domain, cysteine cluster containing domain, cadherin motif containing domain, and coil/coil domain.

To identify and isolate the peptide/solid phase support that interacts and forms a complex with CLASP-2, it is necessary to label or "tag" the CLASP-2 molecule. The CLASP-2 protein can be conjugated to enzymes such as alkaline phosphatase or horseradish peroxidase or to other reagents such as fluorescent labels which can include fluorescein isothiocyanate (FITC), phycoerythrin (PE) or rhodamine. Conjugation of any given label to CLASP-2 can be performed using techniques that are well known in the art. Alternatively, CLASP-2 expression vectors can be engineered to express a chimeric CLASP-2 protein containing an epitope for which a commercially available antibody exist. The epitope-specific antibody can be tagged with a detectable label using methods well known in the art including an enzyme, a fluorescent dye or colored or magnetic beads.

The "tagged" CLASP-2 conjugate is incubated with the random peptide library for 30 minutes to one hour at 22°C to allow complex formation between CLASP-2

and peptide species within the library. The library is then washed to remove any unbound protein. If CLASP-2 has been conjugated to alkaline phosphatase or horseradish peroxidase the whole library is poured into a petri dish containing substrates for either alkaline phosphatase or peroxidase, for example, 5-bromo-4-chloro-3-indoyl phosphate (BCIP) or 3,3',4,4''-diaminobenzidine (DAB), respectively. After incubating for several minutes, the peptide/solid phase- CLASP-2 complex changes color, and can be easily identified and isolated physically under a dissecting microscope with a micromanipulator. If a fluorescent tagged CLASP-2 molecule has been used, complexes can be isolated by fluorescence activated sorting. If a chimeric CLASP-2 protein expressing a heterologous epitope has been used, detection of the peptide/CLASP-2 complex can be accomplished by using a labeled epitope-specific antibody. Once isolated, the identity of the peptide attached to the solid phase support can be determined by peptide sequencing.

In addition to using soluble CLASP-2 molecules, in another embodiment, it is possible to detect peptides that bind to cell-associated CLASP-2 using intact cells. The use of intact cells is preferred for use with cell surface molecules. Methods for generating cell lines expressing CLASP-2 are described in Section 5.8. The cells used in this technique can be either live or fixed cells. The cells can be incubated with the random peptide library and bind to certain peptides in the library to form a "rosette" between the target cells and the relevant solid phase support/peptide. The rosette can thereafter be isolated by differential centrifugation or removed physically under a dissecting microscope. Techniques for screening combinatorial libraries are known in the art (Gallop *et al.*, 1994, J. Med. Chem., 37: 1233; Gordon, 1994, J. Med. Chem., 37: 1385).

As an alternative to whole cell assays for membrane bound receptors or receptors that require the lipid domain of the cell membrane to be functional, CLASP-2 molecules can be reconstituted into liposomes where label or "tag" can be attached.

5.5.4. CLASP-2 Fusion Proteins

In another embodiment of the invention, a CLASP or a modified CLASP sequence can be ligated to a heterologous sequence to encode a fusion protein. For example, for screening of peptide libraries for molecules that bind CLASP-2, it can be useful to produce a chimeric CLASP-2 protein expressing a heterologous epitope that is recognized by a commercially available antibody. A fusion protein can also be engineered to contain a cleavage site located between a CLASP-2 sequence and the heterologous protein sequence, so that the CLASP-2 can be cleaved away from the heterologous moiety. In one embodiment,

fusion proteins of the invention can contain the CLASP-2 extracellular domain comprising at least about residues 1 through 816 or fragment thereof. In another embodiment, fusion proteins can contain the CLASP-2 intracellular domain comprising at least about residue 843 through the end of the CLASP-2 sequence or fragment thereof.

5 **5.6. Cloning Alleles, Variants, and Species Homologs of CLASP-2**

 In order to clone the full length cDNA sequence from any species encoding a CLASP-2 cDNA, or to clone variant forms of the molecule, labeled DNA probes made from nucleic acid fragments corresponding to any partial cDNA disclosed herein can be used to screen a cDNA library derived from lymphoid cells or brain cells. More specifically,

10 oligonucleotides corresponding to either the 5' or 3' terminus of the cDNA sequence can be used to obtain longer nucleotide sequences. Briefly, the library can be plated out to yield a maximum of 30,000 pfu for each 150 mm plate. Approximately 40 plates can be screened. The plates are incubated at 37°C until the plaques reach a diameter of 0.25 mm or are just beginning to make contact with one another (3-8 hours). Nylon filters are placed onto the

15 soft top agarose and after 60 seconds, the filters are peeled off and floated on a DNA denaturing solution consisting of 0.4N sodium hydroxide. The filters are then immersed in neutralizing solution consisting of 1M Tris-HCl, pH 7.5, before being allowed to air dry. The filters are prehybridized in hybridization buffer such as casein buffer containing 10% dextran sulfate, 0.5M NaCl, 50mM Tris-HCl, pH 7.5, 0.1% sodium pyrophosphate, 1% casein, 1%

20 SDS, and denatured salmon sperm DNA at 0.5 mg/ml for 6 hours at 60°C. The radiolabeled probe is then denatured by heating to 95°C for 2 minutes and then added to the prehybridization solution containing the filters. The filters are hybridized at 60°C for 16 hours. The filters are then washed in 1X wash mix (10X wash mix contains 3M NaCl, 0.6M Tris base, and 0.02M EDTA) twice for 5 minutes each at room temperature, then in 1X wash

25 mix containing 1% SDS at 60°C for 30 minutes, and finally in 0.3X wash mix containing 0.1% SDS at 60°C for 30 minutes. The filters are then air dried and exposed to x-ray film for autoradiography. After developing, the film is aligned with the filters to select a positive plaque. If a single, isolated positive plaque cannot be obtained, the agar plug containing the plaques will be removed and placed in lambda dilution buffer containing 0.1M NaCl, 0.01M

30 magnesium sulfate, 0.035M Tris HCl, pH 7.5, 0.01% gelatin. The phage can then be replated and rescreened to obtain single, well isolated positive plaques. Positive plaques can be

isolated and the cDNA clones sequenced using primers based on the known cDNA sequence. This step can be repeated until a full length cDNA is obtained.

It can be necessary to screen multiple cDNA libraries from different tissues to obtain a full length cDNA. In the event that it is difficult to identify cDNA clones encoding the complete 5' terminal coding region, an often encountered situation in cDNA cloning, the RACE (Rapid Amplification of cDNA Ends) technique can be used. RACE is a proven PCR-based strategy for amplifying the 5' end of incomplete cDNAs. 5'-RACE-Ready RNA synthesized from human tissues containing a unique anchor sequence is commercially available (Clontech). To obtain the 5' end of the cDNA, PCR is carried out on 5'-RACE-Ready cDNA using the provided anchor primer and the 3' primer. A secondary PCR reaction is then carried out using the anchored primer and a nested 3' primer according to the manufacturer's instructions. Once obtained, the full length cDNA sequence can be translated into amino acid sequence and examined for certain landmarks such as a continuous open reading frame flanked by translation initiation and termination sites, a cadherin-like domain, an ITAM domain, a tyrosine phosphorylation site, a cysteine cluster, a transmembrane domain, and finally overall structural similarity to the CLASP-2 genes disclosed herein. See, Ponassi *et al.*, 1999, *Mech. Dev.* 80: 207-212; Isakov, 1998, *Receptor Channels* 5: 243-253; Borroto *et al.*, 1997, *Biopolymers* 42: 75-88; Dimitratos *et al.*, 1997, *Mech. Dev.* 63: 127-130; Apperson *et al.*, 1996, *J. Neurosci.* 16: 6839-6852; Ozawa *et al.*, 1990, *Mech. Dev.* 33: 49-56, which discuss protein domains and are incorporated herein by reference.

5.7. Modulating Expression of Endogenous CLASP-2 Genes

Alternatively, the expression characteristics of an endogenous CLASP-2 gene within a cell population can be modified by inserting a heterologous DNA regulatory element into the genome of the cell line such that the inserted regulatory element is operatively linked with the endogenous CLASP-2 gene. For example, an endogenous CLASP-2 gene which is normally "transcriptionally silent", *i.e.*, an CLASP-2 gene which is normally not expressed, or is expressed only at very low levels in a cell population, can be activated by inserting a regulatory element which is capable of promoting the expression of a normally expressed gene product in the cells. Alternatively, a transcriptionally silent, endogenous CLASP-2 gene can be activated by insertion of a promiscuous regulatory element that works across cell types.

A heterologous regulatory element can be inserted into a cell line population, such that it is operatively linked with an endogenous CLASP-2 gene, using techniques, such

as targeted homologous recombination, which are well known to those of skill in the art, (see e.g., in Chappel, U.S. Patent No. 5,272,071; PCT publication No. WO 91/06667, published Jan 16, 1991).

5.8. Anti-CLASP Antibodies

5 Various procedures known in the art can be used for the production of antibodies to epitopes of the natural and recombinantly produced CLASP protein. Such antibodies include, but are not limited to, polyclonal, monoclonal, chimeric, single chain, human or humanized, IgG, IgM, IgA, IgD or IgE, a complementarity determining region, Fab fragments, F(ab')₂ and fragments produced by an Fab expression library as well as anti-
10 idiotypic antibodies. Antibodies which compete for CLASP binding are especially preferred for diagnostics and therapeutics.

 Monoclonal antibodies that bind CLASP-2 can be radioactively labeled allowing one to follow their location and distribution in the body after injection. Radioisotope tagged antibodies can be used as a non-invasive diagnostic tool for imaging *de*
15 *novo* lymphoid tumors and metastases that express CLASP-2.

 Immunotoxins can also be designed which target cytotoxic agents to specific sites in the body. For example, high affinity CLASP-2 specific monoclonal antibodies can be covalently complexed to bacterial or plant toxins, such as diphtheria toxin or ricin. A general method of preparation of antibody/hybrid molecules can involve use of thiol-crosslinking
20 reagents such as SPDP, which attack the primary amino groups on the antibody and by disulfide exchange, attach the toxin to the antibody. The hybrid antibodies can be used to specifically eliminate CLASP-2 expressing lymphocytes.

 For the production of antibodies, various host animals can be immunized by injection with the recombinant or naturally purified CLASP-2 protein, fusion protein or
25 peptides, including but not limited to goats, rabbits, mice, rats, hamsters, and the like. Various adjuvants can be used to increase the immunological response, depending on the host species, including but not limited to Freund's (complete and incomplete), mineral gels such as aluminum hydroxide, surface active substances such as lysolecithin, pluronic polyols, polyanions, peptides, oil emulsions, keyhole limpet hemocyanin, dinitrophenol, and poten-
30 tially useful human adjuvants such as BCG (bacilli Calmette-Guerin) and *Corynebacterium parvum*.

 Monoclonal antibodies to CLASP-2 can be prepared by using any technique which provides for the production of antibody molecules by continuous cell lines in culture.

These include, but are not limited to, the hybridoma technique originally described by Kohler and Milstein, (*Nature*, 1975, 256: 495-497), the human B-cell hybridoma technique (Kosbor *et al.*, 1983, *Immunology Today*, 4: 72; Cote *et al.*, 1983, *Proc. Natl. Acad. Sci. U.S.A.*, 80: 2026-2030) and the EBV-hybridoma technique (Cole *et al.*, 1985, *Monoclonal Antibodies and Cancer Therapy*, Alan R. Liss, Inc., pp. 77-96). In addition, techniques developed for the production of "chimeric antibodies" (Morrison *et al.*, 1984, *Proc. Natl. Acad. Sci. U.S.A.*, 81: 6851-6855; Neuberger *et al.*, 1984, *Nature*, 312: 604-608; Takeda *et al.*, 1985, *Nature*, 314: 452-454) by splicing the genes from a mouse antibody molecule of appropriate antigen specificity together with genes from a human antibody molecule of appropriate biological activity can be used. Alternatively, techniques described for the production of single chain antibodies (U.S. Patent 4,946,778) can be adapted to produce CLASP-2 -specific single chain antibodies. In some embodiments, phage display technology is used to identify antibodies and heteromeric Fab fragments that specifically bind to selected antigens (see, *e.g.*, McCafferty *et al.*, *Nature* 348: 552-554 (1990); Marks *et al.*, *Biotechnology* 10: 779-783 (1992)).

Hybridomas can be screened using enzyme-linked immunosorbent assays (ELISA) in order to detect cultures secreting antibodies specific for refolded recombinant CLASP-2. Cultures can also be screened by ELISA to identify those cultures secreting antibodies specific for mammalian-produced CLASP-2. Confirmation of antibody specificity can be obtained by western blot using the same antigens. Subsequent ELISA testing can use recombinant CLASP-2 fragments to identify the specific portion of the CLASP-2 molecule with which a monoclonal antibody binds. Additional testing can be used to identify monoclonal antibodies with desired functional characteristics such as staining of histological sections, immunoprecipitation of CLASP-2, inhibition of CLASP-2 binding or stimulation of CLASP-2 to transmit an intracellular signal. Determination of the monoclonal antibody isotype can be accomplished by ELISA, thus providing additional information concerning purification or function.

Some anti-CLASP-2 monoclonal antibodies of the present invention are humanized, human or chimeric, in order to reduce their potential antigenicity, without reducing their affinity for their target. Humanized antibodies have been described in the art. See, *e.g.*, Queen, *et al.*, 1989, *Proc. Natl Acad. Sci. U.S.A.* 86: 10029; U.S. Patent Nos. 5,563,762; 5,693,761; 5,585,089 and 5,530,101. The human antibody sequences used for humanization can be the sequences of naturally occurring human antibodies or can be consensus sequences of several human antibodies. See Kettleborough *et al.*, 1991, *Protein*

Engineering 4: 773; Kolbinger *et al.*, 1993, *Protein Engineering* 6: 971. Humanized monoclonal antibodies against CLASP-2 peptides can also be produced using transgenic animals having elements of a human immune system (see, *e.g.*, U.S. Patent Nos. 5,569,825; 5,545,806; 5,693,762; 5,693,761; and 5,7124,350).

5 In some embodiments, an anti-CLASP-2 polypeptide monoclonal or polyclonal antiserum is produced that is specifically immunoreactive with a particular CLASP-2 polypeptide and is selected to have low cross-reactivity against other molecules (*e.g.*, other CLASP polypeptides) and any such cross-reactivity is removed by immunoabsorption prior to use in the immunoassay. Methods for screening and
10 characterizing monoclonal antibodies for specificity are well known in the art and are described generally in Harlow and Lane, *supra*. For example, polyclonal antibodies raised to hCLASP-2A, as shown in SEQ ID NO: 1, or splice variants, or immunogenic portions thereof, can be selected to obtain only those polyclonal or monoclonal antibodies that are specifically immunoreactive with the target protein not with other proteins. This selection
15 may be achieved by subtracting out antibodies that cross-react with molecules. A variety of immunoassay formats may be used to select antibodies specifically immunoreactive with a particular protein. For example, solid-phase ELISA immunoassays are routinely used to select antibodies specifically immunoreactive with a protein (see, *e.g.*, Harlow & Lane, *Antibodies, A Laboratory Manual* (1988) for a description of immunoassay formats and
20 conditions that can be used to determine specific immunoreactivity). Typically a specific or selective reaction will be at least twice background signal or noise and more typically more than 10 to 100 times background. Alternatively, antibodies that cross-react with a selected set of polypeptides may be prepared.

 Antibody fragments which contain specific binding sites of V can be
25 generated by known techniques. For example, such fragments include, but are not limited to, the F(ab')₂ fragments which can be produced by pepsin digestion of the antibody molecule and the Fab fragments which can be generated by reducing the disulfide bridges of the F(ab')₂ fragments. Alternatively, Fab expression libraries can be constructed (Huse *et al.*, 1989, *Science*, 246: 1275-1281) to allow rapid and easy identification of monoclonal Fab
30 fragments with the desired specificity to CLASP-2.

 Anti-CLASP-2 antibodies can also be used to identify, isolate, inhibit or eliminate CLASP-2-expressing cells. In one embodiment, the present invention includes a method of identifying an abnormal T cell profile of an immunocompromised subject relative to the T cell profile of a non-immunocompromised subject. The method includes (i) sorting a

sample of peripheral blood mononuclear cells (PBMC) isolated from the immunocompromised subject into sets of T cell types, (ii) determining the ratio of CLASP-2⁺ cells relative to the total number of cells (CLASP-2⁺: total) in each set, and identifying an abnormal T cell profile in the immunocompromised subject by comparing the CLASP-2⁺: total ratios of sets from the immunocompromised subject with the CLASP-2⁺: total ratios of analogous sets from a non-immunocompromised subject.

In other embodiments, anti-CLASP-2 antibodies can be used for detection of hCLASP-2 protein in assays such as fluorescent activated cell sorting (FACS), ELISA, fluorescent or electron immunomicroscopy, Western blots, gel shift analyses. CLASP-2 expression in various cells, localization within cells, interactions with other proteins, and differentiation between CLASP-2 isoform expression can be determined by use of the techniques listed herein.

5.9. Screening Assays

The invention provides methods for identifying compounds or agents that modulate (*i.e.*, inhibit or enhance) CLASP expression or activity. CLASP expression or activity modulators are useful for treatment of disorders characterized by (or associated with) aberrant or abnormal CLASP expression or activity. Aberrant expression of CLASP mRNA or protein means expression in lymphocytes (*e.g.*, T lymphocytes or B lymphocytes) or other CLASP expressing cells of at least 2-fold, preferably at least 5-fold greater than expression in control lymphocytes obtained from a healthy subject.

The CLASP expression assays can include the steps of contacting a cell expressing CLASP with a compound or agent and assaying CLASP expression. CLASP polypeptide expression is easily measured by ELISA using anti-CLASP-2 antibodies of the invention. CLASP mRNA expression (including expression of specific species or splice variants of CLASP) can be measured by quantitative Northern analysis or quantitative PCR.

CLASP-2 activities include, for example, the CLASP-2 polypeptide binding to PDZ-domain containing molecules and CLASP-2 polypeptide involvement in signal transduction (*e.g.*, leading to T cell activation). Compounds or agents that modulate the interaction of a CLASP-2 polypeptide and a target molecule, modulate CLASP-2 nucleic acid expression, or modulate CLASP-2 polypeptide activity are all contemplated by the methods of the present invention.

Test compounds include, for example, 1) peptides (*e.g.*, soluble peptides, including Ig-tailed fusion peptides and members of random peptide libraries (see, *e.g.*, Lam,

K. S. *et al.*, 1991, Nature 354: 82-84; Houghten, R. *et al.*, 1991, Nature 354: 84-86) and combinatorial chemistry-derived molecular libraries made of D- and/or L-configuration amino acids; 2) phosphopeptides (*e.g.*, members of random and partially degenerate, directed phosphopeptide libraries, see, *e.g.*, Songyang, Z. *et al.*, 1993, Cell 72: 767-778); 3) CLASP-2 antibodies (as described above); 4) small organic and inorganic molecules (*e.g.*, molecules obtained from combinatorial and natural product libraries); 5) antisense RNA and DNA molecules and ribozymes (described above).

The CLASP modulators can be any of a large variety of compounds, both naturally occurring and synthetic, organic and inorganic, and including polymers (*e.g.*, oligopeptides, polypeptides, oligonucleotides, and polynucleotides), small molecules, antibodies, sugars, fatty acids, nucleotides and nucleotide analogs, analogs of naturally occurring structures (*e.g.*, peptide mimetics, nucleic acid analogs, and the like), and numerous other compounds.

In one embodiment, the invention provides assays for screening test compounds which bind to CLASP-2 polypeptides. The assays can be recombinant cell based or cell-free assays. These assays can include the steps of combining a cell expressing a CLASP-2 polypeptide or a binding fragment thereof, and a compound or agent under conditions which allow binding of the compound or agent to the CLASP-2 polypeptide to form a complex. Complex formation can then be determined. The ability of the candidate compound or agent to bind to the CLASP-2 polypeptide or fragment thereof is indicated by the presence of the candidate compound in the complex. Formation of complexes between the CLASP-2 polypeptide and the candidate compound can be quantitated, for example, using standard immunoassays.

In another embodiment, the invention provides screening assays to identify test compounds which modulate the interaction (and most likely CLASP-2 activity as well) between a CLASP-2 polypeptide and a molecule (target molecule with which the CLASP-2 polypeptide normally interacts).

In one embodiment, these CLASP-2 target molecules can be tyrosine kinases (*e.g.*, lyn, lck, fyn, ZAP-70m SyK, and CSK). In another embodiment, these CLASP-2 target molecules can be tyrosine phosphatases (*e.g.*, EZRIN, SHP-1, SHP-2 and PTP36). In another embodiment, these CLASP-2 target molecules can be adaptor proteins (*e.g.*, NCK, CBL, SHC, LNK, SLP-76, HS1, SIT, VAV, GrB2, and BRDG1). In another embodiment, these CLASP-2 target molecules can be cytoskeletal associated proteins such as ankyrin, spectrin, talin, ezrin, tropomyosin, myosin, plectin, syndecans, paralemmin, Band 3 protein,

cytoskeletal protein 4.1, and PTP36. In a further embodiment, CLASP-2 target molecules can be members of the integrin family.

Typically, the assays are recombinant cell based or cell-free assay. These assays can include the steps of combining a cell expressing a CLASP-2 polypeptide or a binding fragment thereof, a CLASP-2 target molecule (*e.g.*, a CLASP-2 ligand) and a test compound, under conditions where but for the presence of the candidate compound, the CLASP-2 polypeptide or biologically active portion thereof binds to the target molecule. Detecting complex formation between the CLASP-2 polypeptide or the binding fragment thereof, the CLASP-2 target molecule and a test compound detecting the formation of a complex which includes the CLASP-2 polypeptide and the target molecule can be accomplished. Detection of complex formation can include direct quantitation of the complex by, for example, measuring inductive effects, such as T cell activation, of the CLASP-2 polypeptide. A significant change, such as a decrease, in the interaction of the CLASP-2 and target molecule (*e.g.*, in the formation of a complex between the CLASP-2 and the target molecule) in the presence of a candidate compound (relative to what is detected in the absence of the candidate compound) is indicative of a modulation of the interaction between the CLASP-2 polypeptide and the target molecule. Modulation of the formation of complexes between the CLASP-2 polypeptide and the target molecule can be quantitated using, for example, an immunoassay. To perform cell free drug screening assays, it is desirable to immobilize either CLASP-2 or its target molecule to facilitate separation of complexes from uncomplexed forms of one or both of the polypeptides, as well as to accommodate automation of the assay. CLASP-2 binding to a target molecule, in the presence and absence of a candidate compound, can be accomplished in any vessel suitable for containing the reactants. Examples of such vessels include microtitre plates, test tubes, and microcentrifuge tubes.

In one embodiment, a fusion polypeptide can be provided which adds a domain that allows the polypeptide to be bound to a matrix. Alternatively, the complexes can be dissociated from the matrix, separated by SDS-PAGE, and the level of CLASP-2-binding polypeptide found in the bead fraction quantitated from the gel using standard electrophoretic techniques.

Other techniques for immobilizing polypeptides on matrices can also be used in the drug screening assays of the invention. For example, either CLASP-2 or its target molecule can be immobilized utilizing conjugation of biotin and streptavidin. Biotinylated CLASP-2 molecules can be prepared from biotin-NHS (N-hydroxy-succinimide) using

techniques well known in the art (*e.g.*, biotinylation kit, Pierce Chemicals, Rockford, Ill.), and immobilized in the wells of streptavidin-coated 96 well plates (Pierce Chemical).

Alternatively, antibodies reactive with CLASP-2 but which do not interfere with binding of the polypeptide to its target molecule can be derivatized to the wells of the plate, and

- 5 CLASP-2 trapped in the wells by antibody conjugation. As described above, preparations of a CLASP-2 -binding polypeptide and a candidate compound are incubated in the CLASP-2 -presenting wells of the plate, and the amount of complex trapped in the well can be quantitated. Methods for detecting such complexes include immunodetection of complexes using antibodies reactive with the CLASP-2 target molecule, or which are reactive with
- 10 CLASP-2 polypeptide and compete with the target molecule; as well as enzyme-linked assays which rely on detecting an enzymatic activity associated with the target molecule.

- One method of drug screening utilizes eukaryotic or prokaryotic host cells which are stably transformed with recombinant DNA molecules expressing the CLASP-2, *e.g.*, the protein having the sequence of SEQ ID NO: 2. Such cells, either in viable or fixed
- 15 form, can be used for standard ligand/receptor binding assays (see, *e.g.*, Parce *et al.* (1989) Science 246: 243-247; and Owicki *et al.* (1990) Proc. Natl Acad. Sci. U.S.A. 87: 4007-4011, which describe sensitive methods to detect cellular responses. A test compound, often labeled, can be assayed for binding or for competition with another ligand for binding. Viable cells could also be used to screen for the effects of drugs on CLASP-2 mediated
- 20 functions, *e.g.*, T cell activation, second messenger levels, and others).

- In another embodiment, the invention provides a method for identifying a compound (*e.g.*, a screening assay) capable of use in the treatment of a disorder characterized by (or associated with) aberrant or abnormal CLASP-2 nucleic acid expression or CLASP-2 polypeptide activity. This method typically includes the step of assaying the ability of the
- 25 compound or agent to modulate the expression of the CLASP-2 nucleic acid or the activity of the CLASP-2 polypeptide thereby identifying a compound for treating a disorder characterized by aberrant or abnormal CLASP-2 nucleic acid expression or CLASP-2 polypeptide activity.

- Methods for assaying the ability of the compound or agent to modulate the
- 30 expression of the CLASP-2 nucleic acid or activity of the CLASP-2 polypeptide are typically cell-based assays. For example, cells which are sensitive to ligands which transduce signals via a pathway involving CLASP-2 can be induced to overexpress a CLASP-2 polypeptide in the presence and absence of a candidate compound. Candidate compounds which produce a change in CLASP-2-dependent responses can be identified. In one embodiment, expression

of the CLASP-2 nucleic acid or activity of a CLASP-2 polypeptide is modulated in cells and the effects of candidate compounds on the readout of interest (such as T cell activation) are measured. For example, the expression of genes which are up- or down-regulated in response to a CLASP-2-dependent signal cascade can be assayed.

5 Alternatively, modulators of CLASP-2 expression can be identified in a method where a cell is contacted with a candidate compound and the expression of CLASP-2 mRNA or polypeptide in the cell is determined. The level of expression of CLASP-2 mRNA or polypeptide in the presence of the candidate compound is compared to the level of expression of CLASP-2 mRNA or polypeptide in the absence of the candidate compound.
10 The candidate compound can then be identified as a modulator of CLASP-2 nucleic acid expression based on this comparison. For example, when expression of CLASP-2 mRNA or polypeptide is greater in the presence of the candidate compound than in its absence, the candidate compound is identified as a stimulator of CLASP-2 nucleic acid expression. Alternatively, when CLASP-2 nucleic acid expression is less in the presence of the candidate
15 compound than in its absence, the candidate compound is identified as an inhibitor of CLASP-2 nucleic acid expression. The level of CLASP-2 nucleic acid expression in the cells can be determined by methods described herein for detecting CLASP-2 mRNA or polypeptide.

 Modulators of CLASP-2 polypeptide activity and CLASP-2 nucleic acid
20 expression identified according to these drug screening assays can be used to treat, for example, immune disorders. These methods of treatment include the steps of administering the modulators of CLASP-2 polypeptide activity or nucleic acid expression, *e.g.*, in a pharmaceutical composition as described in §5.10.1 below, to a subject in need of such treatment, *e.g.*, a subject with a disorder described herein.

25 **5.10. Therapeutic Administration of CLASP-2 Modulators**

 The CLASP-2 protein is expressed in lymphocytes and, as noted *supra*, play a role in regulating T cell and B cell interactions, thus making CLASP-2 activity (*e.g.*, CLASP-2 binding of regulatory proteins) a target for diagnostic and treatment of immune disorders and for modulation of immune function (*e.g.*, T cell activation). Additionally, since CLASP-2
30 contains domains capable of transducing an intracellular signal, cell surface CLASP-2 can be triggered by an anti- CLASP-2 antibody or soluble CLASP-2 or a fragment thereof in order to enhance the activation state of a lymphocyte.

5.10.1. Formulation and Route of Administration

A CLASP-2 polypeptide, a fragment thereof, anti-CLASP-2 antibody, CLASP-2 polynucleotide (*e.g.*, antisense or ribozyme), or small molecule agonists or antagonists can be administered to a subject *per se* or in the form of a pharmaceutical or therapeutic composition. Pharmaceutical compositions comprising the proteins of the invention can be manufactured by means of conventional mixing, dissolving, granulating, dragee-making, levigating, emulsifying, encapsulating, entrapping or lyophilizing processes. Pharmaceutical compositions can be formulated in conventional manner using one or more physiologically acceptable carriers, diluents, excipients or auxiliaries which facilitate processing of the protein or active peptides into preparations which can be used pharmaceutically. Proper formulation is dependent upon the route of administration chosen.

Currently, there are three major classes of protein-derived cell-penetrating peptides that have been used for delivering of proteins into cells and animals (Lindgren, M.; *et al.*, 2000, Trends Pharmacol Sci. 21: 99-103). In one embodiment, the CLASP-2 protein or fragment (encoding a functional domain of CLASP-2) can be introduced into the cell as a fusion protein tied to a transporter protein derived from homeoprotein transcription factors such as ANTP. In another embodiment, the CLASP-2 protein or fragment (encoding a functional domain of CLASP-2) can be introduced into the cell as a fusion protein tied to other transcription factors such as the HIV Tat protein and the herpes simplex virus type 1 (HSV-1) VP22 protein. Members in this family have been widely used in different cellular and animal systems (Schwarze, S.; *et al.*; 2000, Trends Pharmacol Sci. 21: 45-48). In another embodiment, the CLASP-2 protein or fragment (encoding a functional domain of CLASP-2) can be introduced into the cell as a fusion protein tied to peptides derived from signal-sequences present in several proteins such as HIV-1 gp41. In other embodiments, there are several synthetic and/or chimeric cell-penetrating peptides such as transportan and Amphiphilic model peptide (Lindgren, M.; *et al.*, 2000, Trends Pharmacol Sci. 21: 99-103) that can be used. In another embodiment, the CLASP-2 protein or fragment can be introduced by using anti-DNA antibodies (see, *e.g.*, Zack, D. J., *et al.*, 1996, J. Immunol. 157: 2082-8

For topical administration the proteins of the invention can be formulated as solutions, gels, ointments, creams, suspensions, and the like. as are well-known in the art.

Systemic formulations include those designed for administration by injection, *e.g.*, subcutaneous, intravenous, intramuscular, intrathecal or intraperitoneal injection, as well as those designed for transdermal, transmucosal, oral or pulmonary administration.

For injection, the proteins of the invention can be formulated in aqueous
5 solutions, preferably in physiologically compatible buffers such as Hanks's solution, Ringer's solution, or physiological saline buffer. The solution can contain formulatory agents such as suspending, stabilizing and/or dispersing agents. Alternatively, the proteins can be in powder form for constitution with a suitable vehicle, *e.g.*, sterile pyrogen-free water, before use.

For transmucosal administration, penetrants appropriate to the barrier to be
10 permeated are used in the formulation. Such penetrants are generally known in the art.

For oral administration, a composition can be readily formulated by combining the proteins with pharmaceutically acceptable carriers well known in the art. Such carriers enable the proteins to be formulated as tablets, pills, dragees, capsules, liquids, gels, syrups, slurries, suspensions and the like, for oral ingestion by a patient to be treated. For oral
15 solid formulations such as, for example, powders, capsules and tablets, suitable excipients include fillers such as sugars, such as lactose, sucrose, mannitol and sorbitol; cellulose preparations such as maize starch, wheat starch, rice starch, potato starch, gelatin, gum tragacanth, methyl cellulose, hydroxypropylmethyl-cellulose, sodium carboxymethylcellulose, and/or polyvinylpyrrolidone (PVP); granulating agents; and binding
20 agents. If desired, disintegrating agents can be added, such as the cross-linked polyvinylpyrrolidone, agar, or alginic acid or a salt thereof such as sodium alginate.

If desired, solid dosage forms can be sugar-coated or enteric-coated using standard techniques.

For oral liquid preparations such as, for example, suspensions, elixirs and
25 solutions, suitable carriers, excipients or diluents include water, glycols, oils, alcohols, and the like. Additionally, flavoring agents, preservatives, coloring agents and the like can be added.

For buccal administration, the proteins can take the form of tablets, lozenges, and the like. formulated in conventional manner.

For administration by inhalation, the proteins for use according to the present
30 invention are conveniently delivered in the form of an aerosol spray from pressurized packs or a nebulizer, with the use of a suitable propellant, *e.g.*, dichlorodifluoromethane, trichlorofluoromethane, dichlorotetrafluoroethane, carbon dioxide or other suitable gas. In the case of a pressurized aerosol the dosage unit can be determined by providing a valve to

deliver a metered amount. Capsules and cartridges of, *e.g.*, gelatin for use in an inhaler or insufflator can be formulated containing a powder mix of the compound and a suitable powder base such as lactose or starch.

The proteins can also be formulated in rectal or vaginal compositions such as suppositories or retention enemas, *e.g.*, containing conventional suppository bases such as cocoa butter or other glycerides.

In addition to the formulations described previously, the proteins can also be formulated as a depot preparation. Such long acting formulations can be administered by implantation (for example subcutaneously or intramuscularly) or by intramuscular injection. Thus, for example, the proteins can be formulated with suitable polymeric or hydrophobic materials (for example as an emulsion in an acceptable oil) or ion exchange resins, or as sparingly soluble derivatives, for example, as a sparingly soluble salt.

Alternatively, other pharmaceutical delivery systems can be employed. Liposomes and emulsions are well known examples of delivery vehicles that can be used to deliver the proteins or peptides of the invention. Certain organic solvents such as dimethylsulfoxide also can be employed, although usually at the cost of greater toxicity. Additionally, the proteins can be delivered using a sustained-release system, such as semipermeable matrices of solid polymers containing the therapeutic agent. Various sustained-release materials have been established and are well known by those skilled in the art. Sustained-release capsules can, depending on their chemical nature, release the proteins for a few weeks up to over 100 days. Depending on the chemical nature and the biological stability of the therapeutic reagent, additional strategies for protein stabilization can be employed.

As the proteins and peptides of the invention can contain charged side chains or termini, they can be included in any of the above-described formulations as the free acids or bases or as pharmaceutically acceptable salts. Pharmaceutically acceptable salts are those salts which substantially retain the biologic activity of the free bases and which are prepared by reaction with inorganic acids. Pharmaceutical salts tend to be more soluble in aqueous and other protic solvents than are the corresponding free base forms.

5.10.2. Effective Dosages

CLASP-2 polypeptides, CLASP-2 fragments and anti-CLASP-2 antibodies will generally be used in an amount effective to achieve the intended purpose. For use to inhibit an immune response, the proteins of the invention, or pharmaceutical compositions

thereof, are administered or applied in a therapeutically effective amount. By therapeutically effective amount is meant an amount effective ameliorate or prevent the symptoms, or prolong the survival of, the patient being treated. Determination of a therapeutically effective amount is well within the capabilities of those skilled in the art, especially in light of the detailed disclosure provided herein.

For systemic administration, a therapeutically effective dose can be estimated initially from *in vitro* assays. For example, a dose can be formulated in animal models to achieve a circulating concentration range that includes the IC₅₀ as determined in cell culture (*i.e.*, the concentration of test compound that inhibits 50% of CLASP-2 binding interactions).

Such information can be used to more accurately determine useful doses in humans.

Initial dosages can also be estimated from *in vivo* data, *e.g.*, animal models, using techniques that are well known in the art. One having ordinary skill in the art could readily optimize administration to humans based on animal data.

Dosage amount and interval can be adjusted individually to provide plasma levels of the proteins which are sufficient to maintain therapeutic effect. Usual patient dosages for administration by injection range from about 0.1 to 5 mg/kg/day, preferably from about 0.5 to 1 mg/kg/day. Therapeutically effective serum levels can be achieved by administering multiple doses each day.

In cases of local administration or selective uptake, the effective local concentration of the proteins can not be related to plasma concentration. One having skill in the art will be able to optimize therapeutically effective local dosages without undue experimentation.

The amount of CLASP-2 administered will, of course, be dependent on the subject being treated, on the subject's weight, the severity of the affliction, the manner of administration and the judgment of the prescribing physician.

The therapy can be repeated intermittently while symptoms detectable or even when they are not detectable. The therapy can be provided alone or in combination with other drugs. In the case of autoimmune disorders, the drugs that can be used in combination with CLASP-2 or fragments thereof include, but are not limited to, steroid and non-steroid immunosuppressive agents.

5.10.3. Toxicity

Preferably, a therapeutically effective dose of the proteins described herein will provide therapeutic benefit without causing substantial toxicity.

Toxicity of the proteins described herein can be determined by standard pharmaceutical procedures in cell cultures or experimental animals, *e.g.*, by determining the LD₅₀ (the dose lethal to 50% of the population) or the LD₁₀₀ (the dose lethal to 100% of the population). The dose ratio between toxic and therapeutic effect is the therapeutic index.

- 5 The data obtained from these cell culture assays and animal studies can be used in formulating a dosage range that is not toxic for use in human. The dosage of the proteins described herein lies preferably within a range of circulating concentrations that include the effective dose with little or no toxicity. The dosage can vary within this range depending upon the dosage form employed and the route of administration utilized. The exact
- 10 formulation, route of administration and dosage can be chosen by the individual physician in view of the patient's condition. (*See, e.g.*, Fingl *et al.*, 1975, In: The Pharmacological Basis of Therapeutics, Ch.1, p.1).

5.11. Binding Assays

- CLASP-2 polypeptides can be used to screen for molecules that bind to
- 15 CLASP-2 or for molecules to which CLASP-2 binds. The binding of CLASP-2 by the molecule can activate (agonist), increase, inhibit (antagonist), or decrease activity of the CLASP-2 or the molecule bound. Examples of such molecules include antibodies, oligonucleotides, proteins (*e.g.*, receptors), or small molecules. Preferably, the molecule is closely related to the natural ligand of CLASP-2, *e.g.*, a fragment of the ligand, or a natural
- 20 substrate, a ligand, a structural or functional mimetic. (*See*, Coligan *et al.*, Current Protocols in Immunology 1(2): Chapter 5 (1991).) Similarly, the molecule can be closely-related to the natural receptor to which CLASP-2 binds, or at least, a fragment of the receptor capable of being bound by CLASP-2 (*e.g.*, active site). In either case, the molecule can be rationally designed using known techniques.

- 25 Preferably, the screening for these molecules involves producing appropriate cells which express CLASP-2, either as a secreted protein or on the cell membrane. Preferred cells include cells from mammals, yeast, *Drosophila*, or *E. coli*. Cells expressing CLASP-2 (or cell membrane containing the expressed polypeptide) are then preferably contacted with a test compound potentially containing the molecule to observe binding, stimulation, or
- 30 inhibition of activity of either CLASP-2 or the molecule.

The assay can simply test binding of a candidate compound to CLASP-2, where binding is detected by a label, or in an assay involving competition with a labeled

competitor. Further, the assay can test whether the candidate compound results in a signal generated by binding to CLASP-2.

Alternatively, the assay can be carried out using cell-free preparations, polypeptide affixed to a solid support, chemical libraries, or natural product mixtures. The
5 assay can also simply comprise the steps of mixing a candidate compound with a solution containing CLASP-2, measuring CLASP-2 activity or binding, and comparing the CLASP-2 activity or binding to a standard. Preferably, an ELISA assay can measure CLASP-2 level or activity in a sample (*e.g.*, biological sample) using a monoclonal or polyclonal antibody. The antibody can measure CLASP-2 level or activity by either binding, directly or indirectly, to
10 CLASP-2 or by competing with CLASP-2 for a substrate.

In another aspect of the invention, the CLASP-2 polypeptides, or fragments thereof, can be used as "bait proteins" in a two-hybrid assay (see, *e.g.*, U.S. Pat. No. 5,283,317; Zervos *et al.*, 1993, *Cell* 72: 223-232; Madura *et al.*, 1993, *J. Biol. Chem.* 268: 12046-12054; Bartel *et al.*, 1993, *Biotechniques* 14: 920-924; Iwabuchi *et al.*, 1993,
15 *Oncogene* 8: 1693-1696; and Brent WO 94/10300), to identify other proteins, which bind to or interact with CLASP-2 ("CLASP-2-binding proteins" or "CLASP-2-bp") and modulate CLASP-2 polypeptide activity. Such CLASP-2-binding proteins are also likely to be involved in the propagation of signals by the CLASP-2 polypeptides as, for example, upstream or downstream elements of the CLASP-2 pathway.

20 All of these above assays can be used as diagnostic or prognostic markers. The molecules discovered using these assays can be used to treat disease or to bring about a particular result in a patient by activating or inhibiting the CLASP-2 molecule. Moreover, the assays can discover agents which can inhibit or enhance the production of CLASP-2 from suitably manipulated cells or tissues.

25 Therefore, the invention includes a method of identifying compounds or agents that bind to CLASP-2 polypeptides comprising the steps of: (a) contacting a CLASP-2 polypeptide with a compound or agent under conditions which allow binding of the compound to the CLASP-2 polypeptide to form a complex and (b) determining if binding has occurred. Moreover, the invention includes a method of identifying agonists or
30 antagonists comprising the steps of: (a) incubating a candidate compound with CLASP-2, (b) assaying a biological activity, and (b) determining if a biological activity of CLASP-2 has been altered.

Several methods of automating assays have been developed in recent years so as to permit screening of tens of thousands of compounds in a short period. See, *e.g.*, Fodor

et al., 1991, Science 251: 767-773, and other descriptions of chemical diversity libraries, which describe means for testing of binding affinity by a plurality of compounds.

5.12. Other Uses of CLASP Polynucleotides and Polypeptides

The polynucleotides, polypeptides, polypeptide homologues, modulators, and
5 antibodies described herein can be used in one or more of the following methods: a) drug
screening assays; b) diagnostic assays particularly in disease identification, allelic screening
and pharmacogenetic testing; and c) pharmacogenomics. A CLASP-2 polypeptide of the
invention has one or more of the activities described herein and can thus be used to, for
example, modulate an immune response in an immune cell, for example by binding to a
10 CLASP binding partner making it unavailable for binding to the naturally present CLASP
polypeptide.

In one embodiment, these CLASP-2 binding partners can be tyrosine kinases
(*e.g.*, lyn, lck, fyn, ZAP-70m SyK, and CSK). In another embodiment, these CLASP-2
binding partners can be tyrosine phosphatases (*e.g.*, EZRIN, SHP-1, SHP-2 and PTP36). In
15 another embodiment, these CLASP-2 target molecules can be adaptor proteins (*e.g.*, NCK,
CBL, SHC, LNK, SLP-76, HS1, SIT, VAV, GrB2, and BRDG1. In another embodiment,
these CLASP-2 binding partners can be cytoskeletal associated proteins such as ankyrin,
spectrin, talin, ezrin, tropomyosin, myosin, plectin, syndecans, paralemmin, Band 3 protein,
cytoskeletal protein 4.1, and PTP36. In a further embodiment, CLASP-2 binding partners
20 can be members of the integrin family. The isolated nucleic acid molecules of the invention
can be used to express CLASP-2 polypeptide (*e.g.*, via a recombinant expression vector in a
host cell or in gene therapy applications), to detect CLASP-2 mRNA (*e.g.*, in a biological
sample) or a naturally occurring or recombinantly generated genetic mutation in an CLASP-2
gene, and to modulate CLASP-2 activity, as described further below. In addition, the
25 CLASP-2 polypeptides can be used to screen drugs or compounds which modulate CLASP-2
polypeptide activity as well as to treat disorders characterized by insufficient production of
CLASP-2 polypeptide or production of CLASP-2 polypeptide forms which have decreased
activity compared to wild type CLASP-2. Moreover, the anti-CLASP-2 antibodies of the
invention can be used to detect and isolate an CLASP-2 polypeptide, particularly fragments
30 of CLASP-2 present in a biological sample, and to modulate CLASP-2 polypeptide activity.

5.13. Diagnostic Assays

The invention further provides a method for detecting the presence of CLASP, or fragment thereof, in a biological sample. Usually the biological sample contains lymphocytes (*e.g.*, from blood). The method involves contacting the biological sample with a compound or an agent capable of detecting CLASP polypeptide or mRNA such that the presence of CLASP is detected in the biological sample.

A preferred agent for detecting CLASP-2 mRNA is a directly or indirectly labeled nucleic acid probe capable of hybridizing to CLASP-2 mRNA. The nucleic acid probe can be, for example, the full-length CLASP-2 cDNA of SEQ ID NO: 1, or a portion thereof, such as an oligonucleotide of at least 15, 30, 50, 100, 250 or 500 nucleotides in length and sufficient to specifically hybridize under stringent conditions to CLASP-2 mRNA.

A preferred agent for detecting CLASP-2 polypeptide is a directly or indirectly labeled antibody capable of binding to a CLASP-2 polypeptide. Antibodies can be polyclonal, or more preferably, monoclonal. An intact antibody, or a fragment thereof (*e.g.*, Fab or F(ab)₂) can be used. The term “directly or indirectly”, with regard to the probe or antibody, is intended to encompass direct labeling of the probe or antibody by coupling (*i.e.*, physically linking) a detectable substance to the probe or antibody, as well as indirect labeling of the probe or antibody by reactivity with another reagent that is directly labeled. Examples of indirect labeling include detection of a primary antibody using a fluorescently labeled secondary antibody and end-labeling of a DNA probe with biotin such that it can be detected with fluorescently labeled streptavidin. The detection method of the invention can be used to detect CLASP-2 mRNA or polypeptide in a biological sample in vitro as well as in vivo. For example, in vitro techniques for detection of CLASP-2 mRNA include Northern hybridizations and in situ hybridizations. In vitro techniques for detection of CLASP-2 polypeptide include enzyme linked immunosorbent assays (ELISAs), Western blots, immunoprecipitations and immunofluorescence. Alternatively, CLASP-2 polypeptide can be detected in vivo in a subject by introducing into the subject a labeled anti-CLASP-2 antibody. For example, the antibody can be labeled with a radioactive marker whose presence and location in a subject can be detected by standard imaging techniques. Particularly useful are methods which detect the allelic variant of CLASP-2 expressed in a subject and methods which detect fragments of an CLASP-2 polypeptide in a sample.

The invention also encompasses kits for detecting the presence of CLASP-2 in a biological sample. For example, the kit can comprise a directly or indirectly labeled

compound or agent capable of detecting CLASP-2 polypeptide or mRNA in a biological sample; means for determining the amount of CLASP-2 in the sample; and means for comparing the amount of CLASP-2 in the sample with a standard. The compound or agent can be packaged in a suitable container. The kit can further comprise instructions for using the kit to detect CLASP-2 mRNA or polypeptide.

The methods of the invention can also be used to detect naturally occurring genetic mutations in an CLASP-2 gene, thereby determining if a subject with the mutated gene is at risk for a disorder characterized by aberrant or abnormal CLASP-2 nucleic acid expression or CLASP-2 polypeptide activity as described herein. In preferred embodiments, the methods include detecting, in a sample of cells from the subject, the presence or absence of a genetic mutation characterized by at least one of an alteration affecting the integrity of a gene encoding an CLASP-2 polypeptide, or the misexpression of the CLASP-2 gene.

5.14. Biological Activities of CLASP-2

As described herein, CLASP polypeptides mediates a variety of cell functions in lymphocytes and other cells. As described herein, a variety of assays are useful for detecting or quantitating CLASP activity, or for identifying agents (including polynucleotides, polypeptides, and antibodies of the invention) that modulate CLASP activity (*i.e.*, biological activity, *e.g.*, binding) or expression. Such agents are useful for treatment of diseases and conditions associated with aberrant CLASP expression or activity. Further, following the guidance provided herein, other CLASP-mediated activities can be identified by those of skill using routine assays, such as those described below.

Exemplary assays for CLASP function (or modulation of function) include assays for modulation of an *in vitro* or *in vivo* cell response (*e.g.*, an immune response such as lymphocyte activation, antibody production, inflammation) by detecting a change in an activity (*e.g.*, cytokine production, calcium flux, tyrosine phosphorylation, regulation of early activation markers, cell metabolism, proliferation, and the like, as described below) of cells *in vitro* or *in vivo*. In one embodiment, the cells are lymphocytes.

In one assay, for example, recombinant CLASP-2 protein, peptides, or antibodies corresponding to the CLASP-2 extracellular domain can be mixed directly with T and B cells. Cytokine production by these cells can then be measured and the degree of modulation of the immune response quantitated. Alternatively, antigen-presenting B cells are mixed with untransfected T cells or T cells that have been transfected with CLASP-2 isoforms. Cytokine production (or calcium flux or other assays in §5.14.3) is be measured at

the appropriate time to determine the effect of CLASP-2 on such an immune response. In a similar assay, B cells transfected with CLASP-2 constructs are tested for their ability to stimulate a T cell to generate an immune response. Transfected constructs in any of these cases could encode, for example, full or partial length CLASP-2 sequences, or antisense constructs to inhibit translation of endogenous CLASP-2 gene. Any of the examples described herein can be used to stimulate an immune response in the presence or absence of CLASP-2 isoforms or antibodies and assay the resulting effects on immune response by the methods listed in §5.14.3.

5.14.1 Methods for Generating an Immune Response in vitro

In various assays, an effect of an agent on immune cells is detected using an *in vitro* assay. The degree of an immune response can be measured or quantitated by a number of standard assays including those described below.

In one assay, human peripheral blood mononuclear cells (PBMC), human T cell clones (*e.g.*, Jurkat E6, ATCC TIB-152), EBV-transformed B cell clones (*e.g.*, 9D10, ATCC CRL-8752), antigen-specific T cell clones or lines can be used to examine immune responses *in vitro*. Activation, enhanced activation or inhibition of activation of these cells or cell lines can be used for the evaluation of potential CLASP therapeutics. Standard methods by which hematopoietic cells are stimulated to undergo activation characteristic of an immune response are, for example:

A) Antigen specific stimulation of immune responses. Either pre-immunized or naïve mouse splenocytes can be generated by standard procedures. In addition, antigen-specific T cell clones and hybridomas (*e.g.*, MBP-specific), and numerous B cell lymphoma cell lines (*e.g.*, CH27), have been previously characterized are available for the assays discussed below. Antigen specific splenocytes or B-cells can be mixed with specific T-cells in the presence of antigen to generate an immune response. This can be performed in the presence or absence of CLASP-2 to assay whether CLASP-2 modulates the immune response as measured by any of the assays in section 5.14.2.

B) Non-specific T cell activation. The following methods can be used to activate T cells in the absence of antigen: 1) cross-linking T cell receptor (TCR) by addition of antibodies against receptor activation molecules (*e.g.*, TCR, CD3, or CD2) together with antibodies against co-stimulator molecules, for example anti-CD28; 2) activating cell surface receptors in a non-specific fashion using lectins such as concanavalin A (con A) and phytohemagglutinin (PHA); 3) mimicking cell surface receptor-mediated activation using

pharmacological agents that activate protein kinase C (*e.g.*, phorbol esters) and increase cytoplasmic Ca^{2+} (*e.g.*, ionomycin).

C) Non-specific B cell activation: 1) application of antibodies against cell surface molecules such as IgM, CD20, or CD21. 2) Lipopolysaccharide (LPS), phorbol esters, calcium ionophores and ionomycin can also be used to by-pass receptor triggering.

D) Mixed lymphocyte reaction (MLR). Mix donor PBMC with recipient PBMC to activate lymphocytes by presentation of mismatched tissue antigens, which occurs in all cases except identical twins.

E) Generation of a specific T cell clone or line that recognizes a particular antigen. A standard approach is to generate tetanus toxin-specific T cells from a donor that has recently been boosted with tetanus toxin. Major histocompatibility complex- (MHC-) matched antigen presenting cells and a source of tetanus toxin are used to maintain antigen specificity of the cell line or T cell clone (Lanzavecchia, A., *et al.*, 1983, Eur. J. Immun. 13: 733-738).

The anticipated mechanism of action of a CLASP polypeptide or polynucleotide should define the appropriate assay to use to investigate its potential enhancement or inhibition of lymphocyte activation. For example, soluble proteins containing the CLASP extracellular domain may interfere with the interaction between T cells and antigen presenting cells. Such interaction plays a role in the MLR and in antigen-specific T cell activation, but not in non-specific T or B cell activation. The assays described above have the advantage of several possible detection methods for quantitation.

5.14.2. Methods for Generating an Immune Response in vivo

In various assays, an effect of an agent on immune cells is detected using an *in vivo* assay. The degree of an immune response can be measured or quantitated by a number of standard assays including those described below.

(A) Animal Model for Transplantation Rejection: Ectopic Heart Transplantation

In one embodiment, a standard animal model for graft versus host rejection is ectopic heart transplantation (Fulmer *et al.*, 1963, Am. J. Anat. 113: 273-281). This method involves using BALB/C mice (either sex, and range from 1–9 months) for transplanting cardiac tissue into a surgically-created pocket on the dorsum for both ears made by slitting the skin over the auricular artery at the base of the ear. Small curved forceps are forced into the slit, bluntly dissecting between the skin and the cartilage plate. Donor tissue is eased into

the base of the pocket near the distal edge of the ear. The auricular artery is used to seal off the opening of the pocket. Within 10 to 14 days pulsatile activity of the transplant should be observed. Gross appearance of the graft, patterns of vacuolar supply to the graft area and pulsatile activity can be easily observed utilizing transilluminated light during the first three weeks post-transplantation. Follow-up can continue for several months.

(B) Animal model for Autoimmune Disease: Induction of Collagen Induced Arthritis (CIA)

Collagen Induced Arthritis (CIA) is a standard model for studying progression and immune (Courtenay *et al.*, 1980, Nature 283: 666 and Wooley *et al.*, 1981, J. Exp. Med. 154: 688). DBA/a mice can be used as an assay for the in vivo relevance of CLASP-2 in vitro testing potential immune therapeutics. In vivo experiments will be performed to examine the ability of potential therapeutics to prevent CIA. We will use 3-5 mice per group to statistically justify our results.

Once a titer of the potency of collagen type II (CII) is obtained therapeutics can be tested. In one embodiment, three mice will be immunized with three different concentrations of CII 50, 200, and 400 µg per animal (Nabozny *et al.*, 1996, J. Exp. Med., 183: 27-37). To induce CIA, animals can be immunized with an appropriate concentration of CII, determined as described above. One half of a 1:1 ratio of antigen:CFA can be injected at the base of the tail and the remainder equally divided in each hind footpad. Mice can be carefully monitored every day for the onset and progression of CIA throughout the experiment until its termination 12 weeks post-immunization with CII. The pieces of heart transplanted can be approximately 3 X 3 mm in size. The severity of arthritis can be assessed following standard procedures known to one of skill in the art.

5.14.3 Assay Quantitation

(A) Tyrosine phosphorylation

Tyrosine phosphorylation of early response proteins such as HS1, PLC- γ , ZAP-70, and Vav is an early biochemical event following T cell activation. The tyrosine phosphorylated proteins can be detected by Western blot using antibodies against phosphorylated tyrosine residues. Tyrosine phosphorylation of these early response proteins can be used as a standard assay for T cell activation (J. Biol. Chem., 1997, 272(23): 14562-14570). Any change in the phosphorylation pattern of these or related proteins when immune responses are generated in the presence of CLASP is indicative of a CLASP modulation of this response.

(B) Intracellular Calcium Flux

The kinetics of intracellular Ca^{2+} concentrations are measured over time after stimulation of cells preloaded with a calcium sensitive dye. Upon binding the Ca^{2+} indicator dye, Fluor-4 (Molecular Probes), exhibits an increase in fluorescence level using flow cytometry, solution fluorometry, and confocal microscopy. Any change in the level or timing of calcium flux when immune responses are generated in the presence of CLASP is indicative of a CLASP modulation of this response

(C) Regulation of early activation markers

Increased and diminished expression/regulation of early lymphocyte activation marker levels such as CD69, IL-2R, MHC class II, B7, and TCR are commonly measured with fluorescently labeled antibodies using flow cytometry. All antibodies are commercially available. Any change in the expression levels of lymphocyte activation markers when immune responses are generated in the presence of CLASP is indicative of a CLASP modulation of this response.

(D) Increased metabolic activity/acid release

Activation of most known signal transduction pathways trigger increases in acidic metabolites. This reproducible biological event is measured as the rate of acid release using a microphysiometer (Molecular Devices), can be used as an early activation marker when comparing the treatment of cells with potential biological therapeutics (McConnell, H.M. *et al.*, 1992, Science 257: 1906-1912 and McConnell, H.M., 1995, Proc. Natl. Acad. Sci. 92: 2750-2754). Any statistically significant increase or decrease in acid release of CLASP-treated sample, as compared to control sample (no treatment), suggest an effect of CLASP on biological function.

(E) Cell proliferation/cell viability assays

(1) ^3H -thymidine incorporation

Exposure of lymphocytes to antigen or mitogen in vitro induces DNA synthesis and cellular proliferation. The measurement of mitotic activity by ^3H -thymidine incorporation into newly synthesized DNA is one of the most frequently used assays to quantitative T cell activation. Depending on the cell population and form of stimulation used to activate the T cells, mitotic activity can be measured within 24-72 hrs. in vitro, post ^3H -thymidine pulse (Mishell, B. B. and S. M. Shiigi, 1980, Selected Methods in Cellular Immunology, W. H. Freeman and Company and Dutton, R. W. and Pearce, J. D., 1962, Nature 194: 93). Any statistically significant increase or decrease in CPM of CLASP -treated

sample, as compared to control sample (no treatment), suggest an effect of CLASP on biological function.

(2) MTS [5-(3-carboxymethoxyphenyl)-2-(4,5-dimethylthiazolyl)-3-(4-sulfophenyl)tetrazolium, inner salt] is a colorimetric method for determining the number of viable cells in proliferation or cytotoxicity assays (Barltrop, J.A. *et al.*, 1991, *Bioorg. & Med. Chem. Lett.* 1: 611). 1-5 days after lymphocyte activation, MTS tetrazolium compound, Owen's reagent, is bio-reduced by cells into a colored formazan product that is soluble in tissue culture media. Color intensity is read at 490 nm minus 650 nm using a microplate reader. Any statistically significant increase or decrease in color intensity of CLASP-treated sample, as compared to control sample (no treatment), can suggest an effect of CLASP on biological function (Mosmann, T., 1983, *J. Immunol. Methods* 65: 55 and Barltrop, J.A. *et al.* (1991)).

(3) Bromodeoxyuridine (BrdU), a thymidine analogue, readily incorporates into cells undergoing DNA synthesis. BrdU-pulsed cells are labeled with an enzyme-conjugated anti-BrdU antibody (Gratzner, H.G., 1982, *Science* 218: 474-475.). A colorimetric, soluble substrate is used to visualize proliferating cells that have incorporated BrdU. Reaction is stopped with sulfuric acid and plate is read at 450 nm using a microplate reader. Any statistically significant increase or decrease in color intensity of CLASP-treated sample, as compared to control sample (no treatment), suggest an effect of CLASP on biological function.

(F) Apoptosis by Annexin V

Programmed cell death or apoptosis is an early event in a cascade of catabolic reactions leading to cell death. A loss in the integrity of the cell membrane allows for the binding of fluorescently conjugated phosphatidylserine. Stained cells can be measured by fluorescence microscopy and flow cytometry (Vermes, I., 1995, *J. Immunol. Methods* 180: 39-52). In one embodiment, any statistically significant increase or decrease in apoptotic cell number of CLASP-treated sample, as compared to control sample (no treatment), suggest an effect of CLASP on biological function. For evaluating apoptosis *in situ*, assays for evaluating cell death in tissue samples can also be used in *in vivo* studies.

(G) Quantitation of cytokine production

Cell supernatants harvested after cell stimulation for 16-48 hrs are stored at -80°C until assayed or directly tested for cytokine production. Multiple cytokine assays can be performed on each sample. IL-2, IL-3, IFN- γ and other cytokine ELISA Assays are available for mouse, rat, and human (Endogen, Inc. and BioSource). Cytokine production is

measured using a standard two-antibody sandwich ELISA protocol as described by the manufacturer. The presence of horseradish peroxidase is detected with 3, 3',5, 5' tertamethylbenzidine (TMB) substrate and the reaction is stopped with sulfuric acid. The absorbency at 450 nm is measured using a microplate reader. Any statistically significant increase or decrease in color intensity of CLASP-treated sample, as compared to control sample (no treatment), suggest an effect of CLASP on biological function.

(H) NF-AT can be visualized by Immunostaining

T cell activation requires the import of nuclear factor of activated T cells (NFAT) to the nucleus. This translocation of NF-AT can be visualized by immunostaining with anti-NF-AT antibody (Cell 1998, 93: 851-861). Therefore, NF-AT nuclear translocation has been used to assay T cell activation. Similarly, NF-AT/luciferase reporter assays have been used as a standard measurement of T cell activation (MCB 1996, 12: 7151-7160).

(I) ELISA for collagen type II (CII)-specific antibodies (see above for related in vivo assay)

C(II) titers from serum of animals immunized with CLASP-2 can be measured and compared. Both TH1-dependent IgG2a and TH2-dependent IgG1 and IgE CII-specific antibody isotypes will be measured by ELISA. Mouse blood will be obtained by orbital bleed one and two months post-immunization with CII. Samples will be allowed to coagulate and centrifuge to obtain sera, and stored at -80°C until assayed by ELISA. Coat ELISA plates with CII and dilute sera. HRP conjugated goat, isotype specific antibody. Plates are then expose to TMB substrate and read at 450 nm using a microplate reader (Nabozny *et al.*, 1996, J. Exp. Med. 183: 27-37). Any change in the levels of Collagen specific antibodies by colorimetric test when immune responses are generated in the presence of CLASP is indicative of a CLASP modulation of this response.

(J) Antibody Production by ELISPOT Assay

A solid-phase enzyme-linked immunospot (ELISPOT) assay for the quantification of isotype-specific antibody secreting cells (Czerkinsky *et al.*, 1983, J Immunol. Methods. 65: 109-121). Both human and mouse B cells can be tested for isotype and antigen specific antibody production. Although based on a standard ELISA, this technique becomes more sensitive by detecting antibody secretion from single cells. Any change in ELISPOT levels when immune responses are generated in the presence of CLASP is indicative of a CLASP modulation of this response.

(K) Cellular degranulation following IgE cross-linking.

Two cell lines have been obtained from ATCC (MEG01 and HEL-17.92), both of which express the human FCεR1 receptor. FCεR1 is the high affinity receptor for IgE complexes, which when coupled to biotin can be cross-linked with avidin to induce degranulation and histamine release of lymphocytes. Following acylation of the sample, histamine is quantified with an enzyme immunoassay competition assay (Immunotech). Histamine release. A statistically significant increase or decrease in histamine concentration of a CLASP-2 treated sample, as compared to control sample (no treatment), suggest an effect of CLASP-2 on biological function. Any change in frequency of degranulation or histamine levels when immune responses are generated in the presence of CLASP is indicative of a CLASP modulation of this response.

(L) Cellular phenotyping of lymphocytes by flow cytometry and Immunocytochemistry

Determining the tissue distribution of lymphocytes following a pathological disorder can aid in identifying specific organ, tissue and lymphocyte involved in an immune response. Cellular phenotyping of lymphocyte trafficking is generally performed with by flow cytometry and Immunocytochemistry. There are several cluster determination (CD) molecules that are routinely used to identify phenotype, activation kinetics, and regulation events of cells. Any change in levels or distribution of CD molecules when immune responses are generated in the presence of CLASP is indicative of a CLASP modulation of this response.

(M) Structure/Function Assays: Homotypic and/or Heterotypic, Calcium-dependant Cell Adhesion

L929 cells can be transfected with CLASP and Neomycin. G418-resistant clones can be screened for CLASP-expression with anti-CLASP peptide-specific antibodies. These CLASP-expressing clones can then be used to test for homotypic and/or heterotypic calcium dependent cell adhesion using the “cell aggregation assay” described for cadherin molecules (Murphy-Erdosh, C. *et al.*, 1995, J. Cell Biol. 129: 1379-1390). Any change in the levels of cellular aggregation when immune responses are generated in the presence of CLASP-2 is indicative of a CLASP-2 modulation of this response.

The following cDNA clones described in the Specification and further described in the Examples below have been deposited with the American Type Culture Collection, 10801 University Boulevard, Manassas, VA 20110-2209 under the Budapest Treaty on March 24, 2000 and given the Accession Nos. indicated:

hCLASP-2A 3' clone (AVC-PD1) ATCC accession number PTA-1563

hCLASP-2A 5' clone (AVC-PD2) ATCC accession number PTA-1562

hCLASP-2B clone (AVC-PD12) ATCC accession number PTA-1573

5 The following cDNA clones described in the Specification and further described in the Examples below have been deposited with the American Type Culture Collection, 10801 University Boulevard, Manassas, VA 20110-2209 under the Budapest Treaty on October 17, 2000 and given the Accession Nos. indicated:

hCLASP-2 clone hC2GR3.3 (AVC-PD14) ATCC Accession No. PTA-2611

hCLASP-2 clone hC2RT (AVC-PD19) ATCC Accession No. PTA-2614

10

6. EXAMPLES

EXAMPLE 1

Cloning of CLASP-2

The cloning of the CLASP gene family has not been a straightforward process.

5 The cloning of each CLASP family member required the use of multiple techniques and resources. CLASP-2 was cloned in the following manner: an expressed sequence tag or EST clone (IMAGE clone 815795, derived from human germinal B cells) was identified based on a BLAST search of human GenBank human EST database using CLASP-1 sequences. IMAGE clone 815795 was sequenced completely. A polynucleotide probe prepared from
10 815975 sequence was labeled with ³²P-dCTP and used to screen human cDNA libraries including Jurkat (Stratagene) and Ramos B cell cDNA library (James Boulter, UCLA). The screening methods employed were as described in Maniatis *et al.*, 1989, Molecular Cloning A Laboratory Manual, Cold Spring Harbor Laboratory, New York. Several clones were identified and clone C9, with an insert of 3,752 base pairs, was sequenced (ABI dye-
15 sequencing system, PE Applied Biosystems; Perkin-Elmer Corporation, 761 Main Avenue, Norwalk, CT, U.S.A.). A 5' probe was prepared from C9 sequence and used to rescreen the cDNA libraries. Several clones were isolated, but could not be excised from the phage (Stratagene, CA) without deleting the insert. To circumvent this problem, anchor PCR was performed using M13F primer and CLASP-2 primer (C96AS). The PCR fragment was
20 cloned using the pGEM-T system (Promega), although initial attempts were unsuccessful. The isolated sequence encompassed additional but incomplete cDNA sequence and was determined to carry at least one mutation that may have allowed it to be propagated in bacteria. Commercial libraries from multiple tissue sources including human placenta, B cell, T cell and peripheral blood were exhaustively screened and re-screened resulting in the
25 acquisition of only partial cDNAs. Generation of cDNA libraries using oligo dT or CLASP-specific primers also resulted in the acquisition of partial cDNAs. Genomic libraries were screened to obtain a portion of the genomic locus for each of the CLASP genes, and a genomic walk was initiated to obtain 5' exons and extend the cDNA sequence.

To obtain additional 5' CLASP-2 sequence, portions of the cDNA and
30 genomic sequence from a BAC (Bacterial Artificial Chromosome) genomic library were compared to the NCBI database by BLAST. A genomic clone (Genbank identifier: gi9988160) comprising random, shotgun genomic sequence was identified. Using TFASTX (Pearson and Lipman, PNAS (1988) 85:2444-2448), the amino-terminal sequence of human

CLASP4 was compared to 6 frame translation of gi9988160. Areas of gi9988160 that encoded amino acids with high similarity to CLASP4 amino acid sequence were used to design CLASP-2-specific oligonucleotides for RTPCR (reverse transcriptase polymerase chain reaction according to manufacturers instructions: Reverse transcriptase Gibco/BRL, Taq Polymerase from Sigma). Using oligonucleotides hC2gS5 (nucleotides -66 to -44 of FIG. 11) and C2AS18 (reverse complement of nucleotides 2120 to 2140 of FIG. 11) an RTPCR product of approximately 2.2kb was generated, sequenced (dideoxynucleotide termination sequencing, Beckman Coulter CEQ2000) and shown to be additional human CLASP-2 5' sequence. Further complicating the cloning full-length CLASP cDNA products was the difficulty to clone (and subclone) certain CLASP cDNA products. Standard isolation of some of the CLASP cDNAs from a pure phage population following screening of commercially available cDNA libraries ("ZAP-out" procedure, Stratagene) resulted in no bacterial colonies. Similarly, certain RT-PCR products could not be cloned into standard plasmid vectors. No colonies were isolated by cloning these fragments into vectors lacking promoters, reverse orientations, low copy vectors, or by growth at altered temperatures or levels of antibiotic for plasmid selection (examples: CLASP-7 - HC7gS6 to HC7gAS1 and HC7gS3 to HC7AS14; CLASP-4 - C4P2 to hC4ASTM and C4P2 to HC4AS3'; CLASP-1 - hC1S5' to hC1AS3'Kpn and C1S7 to hC1AS3'Kpn; see Primer Table below). One possibility is that sequences contained within certain regions of CLASP cDNAs are bacteriicidal and therefore not amenable to cloning. To circumvent these problems direct sequencing of RT-PCR products was performed.

Primer Table

CLASP gene	Sense Primer	Sense sequence	Antisense Primer	Antisense sequence
CLASP-7	HC7gS5	AGGCCTTGCTCTGTTTACCTG	HC7gAS1	TGTCATGTACTGCACTCGCACAGC
CLASP-7	HC7gS3	ACAGGAACCTGCTGTACGTGTAC	HC7AS14	TCGTGGCTGCACAGGATGCGGGTG
CLASP-4	C4P2	GACCCATTAGGAGGTCTAC	HC4AS3'	CGGGATCCATTGTCACCGTACATCTGC
CLASP-4	C4P2	GACCCATTAGGAGGTCTAC	HC4AS3'	CGGGATCCATTGTCACCGTACATCTGC
CLASP-1	hC1S5'	TATGTCTCAGTCACCTACCTG	HC1AS3'Kpn	CTTGGTACCACTTCAGCACTAGATGAGATG
CLASP-1	C1S7	TCAAGACCAGGGCATGCAAG	HC1AS3'Kpn	CTTGGTACCACTTCAGCACTAGATGAGATG

In-frame stop codons were not present suggesting that the cDNA was not full length. To obtain the 5' terminus of CLASP-2 5' RACE was employed. Antisense oligonucleotides directed against the 5' end of the longest CLASP-2 sequence were generated:

Primers used for human CLASP-2 5' RACE

	<u>primer</u>	<u>sequence(5' TO 3')</u>	<u>nucleotide position</u>
10	HC2RACE1	AAGAGCAGCATCTCCCGTAAACAGTC	-15 to 11
	HC2RACE2	TAACAAGCTCTGTGCTTCCTCTTCCG	414 to 443
	HC2RACE3	ACCACTTTGTTCGGAAGCTGTCGAAACTC	512 to 540
15	HC2RACE4	TTTGTACAGCCAGCCATGCTTGGTGATC	634 to 661

RACE was carried out using Generacer kit (Invitrogen) according to manufacturers specifications using polyA selected mRNA from 9D10 B cell tissue culture line. The sequence of the oligonucleotides presented is the reverse complement (*i.e.*, antisense) of the the CLASP1 cDNA at the indicated position based upon numbering in FIG. 11.

The full length cDNA (presented in FIG. 11) is therefore a compilation of cDNA from cDNA libraries, RTPCR products and 5' RACE products. The sequence of the CLASP-2 cDNA is shown in FIG. 11.

EXAMPLE 2

5 Tissue and Cell Line Expression of the CLASP-2 gene

Multiple Tissue Northern blots were purchased from Clontech; hybridization procedures were followed according to manufacturer's procedures and recommendations. Human T cell line (Jurkat), human myelomonocyte cells (MV4-11), B cells (9D10), monocytes (THP-1), mouse T cells (3A9), mouse B cells (CH27), human promyelocyte
10 (HL60) and human kidney epithelial cells (293 cell line) were maintained as cultured cell lines. For Multiple Cell Northern, RNA was prepared from cell suspensions using the GIBCO-BRL Trizol system. All steps were performed according to the manufacturer's procedures and recommendations. RNA concentrations were determined by the 260nm/280nm light absorption of the RNA solution. 20 µg RNA was ethanol precipitated and
15 resuspended in formamide/formaldehyde buffer and incubated for 15' at 65°C to eliminate putative secondary structures. RNA samples were run over night on a 1.1% agarose gel containing 1.5% formaldehyde (both gel and running buffer were 20 mM sodium phosphate, pH 7.5). To visualize RNA after gel migration, approx. 0.5 µg ethidium bromide was added to each sample prior to the run together with RNA loading buffer. RNA in the gel was then
20 visualized by 260nm wavelength light. After soaking the gel for 15' in deionized water to reduce the concentration of ethidium bromide in the gel, the RNA was transferred onto Amersham Hybond-N plus membrane by capillary blotting in 20 x SSC buffer for 5 hours. Subsequent to blotting, the membrane was washed in 5 x SSC for 3' and RNA was crosslinked to the membrane by UV light (Stratagene Stratalinker).

25 A probe which recognizes CLASP-2 isoforms A, B, C, and D (probe HC2.2) was used. Probe HC2.2 encompasses to nucleotides 3920 to 4650 (731 bp long) of CLASP-2A. The HC2.2 probe was prepared using standard labeling kits and desalted using pasteur pipette G-50 Sephadex column in TEN (10 mM Tris-HCl, pH 8.0, 1 mM EDTA, and 100 mM NaCl).

30 Hybridizations of ³²P dCTP labeled DNA probes to the membrane bound RNAs (multiple tissue and multiple cells) were carried out in CLONTECH EXPRESSHYB solution, at 68°C and for 1-2 hours. Blots were washed 2 times in 2x SSC 0.1% SDS for 10' each at 50°C and then twice in 0.2 x SSC 0.1% SDS for 10' each at 50°C, followed by a 5'

wash in 2xSSC at 50°C. Exposure to KODAK BIOMAX MS film was carried out at minus 80°C using amplifying screens. Typical exposure times were 10 to 36 hours.

EXAMPLE 3

Southern Analysis of CLASP-2

5 BAC DNA was prepared from E. coli over night cultures using the QIAGEN DNA preparation system. All preps were performed according to the manufacturer's procedures, including the modifications for low copy number DNA constructs. Genomic DNA was prepared from HeLa cells (ATCC #CCL-17) using the methods described by Sambrook, Fritsch and Maniatis (1989); DNA concentrations were determined by the 260nm
10 light absorption of the DNA solution, and aliquots corresponding to 20 microgram (µg) genomic DNA or 2 µg for BAC DNA were used for restriction enzyme digests with Eco RI or Hind III (genomic DNA) or Eco RI and Pst I (BAC DNA). Digests were carried out in 150 microliter volume for 4 hours at 37°C. Digested DNA was ethanol precipitated and the pellet was resuspended in 20 microliter deionized water prior to migration over a 1.2 %
15 agarose gel at 35 V over night. Running buffer was TAE, and the gel contained 0.1 µg ethidium bromide/ml to visualize DNA.

Subsequent to gel separation, DNA was visualized by 260 nm wavelength light. The gel was then washed twice for 20' in denaturing buffer (0.5M NaCl, 0.4 N NaOH) and twice in neutralization buffer (1.5 M NaCl, 0.5 M TRIS pH 8.0). DNA was transferred
20 from the gel onto AMERSHAM HYBOND N membrane by capillary blotting in 20 x SSC for 5 hours. The DNA was crosslinked to the membrane by UV light using a Stratagene Stratalinker.

A probe, HC2.1, which recognizes CLASP-2, was used. Probe HC2.1 encompasses nucleotides 325 to 1126 (802 bp long) of CLASP-2A. The HC2.1 probe was
25 prepared using standard labeling kits and desalted using pasteur pipette G-50 Sephadex column in TEN (10 mM Tris-HCl, pH 8.0, 1 mM EDTA, and 100 mM NaCl). Hybridizations of ³²P dCTP labeled DNA against DNA immobilized onto the membrane were carried out at 65°C overnight in modified CHURCH hybridization solution (7% SDS, 0.5 M sodiumphosphate, 1mM EDTA). Membranes were then exposed to KODAK BIOMAX MS
30 film at minus 80°C. Typical exposure times were 12 hours for genomic DNA southern analysis and 3 hours for BAC DNA Southern analysis.

The genomic DNA southern analysis revealed two fragments (~4.5 kb and 1.85 kb) in the Eco RI digested DNA but three fragments in BACs 4 and 6 DNA. The two major bands are identical in both genomic and BAC DNA (FIG. 7).

EXAMPLE 4

CLASP-2 Genomic Cloning

Genomic clones of human CLASP-2 were obtained using the Release I high density filters from Genome Systems Inc (cat # FBAC-4434). Two rounds of screening were completed. The first round of screening was carried out using a probe corresponding to nucleotides 3830 to 4558 of the human CLASP-2 cDNA by standard protocols specific by Genome Systems. This screen identified two genomic clones, referred to as AVC BAC4 and 7. A second round of screening using a probe that corresponded to nucleotides 1208 to 1604 of human CLASP-2 cDNA identified clone AVC BAC26. All the clones were partially sequenced to authenticate that they were indeed CLASP-2 genomic clones, to verify exon sequences, and to identify exon/intron boundaries. Oligonucleotides for sequencing the BACs were based upon human CLASP-2 cDNA sequence. Sense and antisense sequencing oligonucleotides were designed along the length of the human CLASP-2 cDNA spaced approximately every 200 nucleotides to ensure a high density of coverage of the corresponding genomic regions. Sequencing reactions with primers and BAC DNA were carried out by standard PCR sequencing using Big Dye termination sequencing mix (ABI). Results from sequence reactions were analyzed using Sequencher software (Genecodes). The results are summarized in FIG. 6.

EXAMPLE 5

Expression of Recombinant CLASP-2A Polypeptide in Bacterial Cells

Portions of hCLASP-2 were cloned into the GST expression vector pGEX (Pharmacia). These include the region spanning the potential Cadherin processing site through 200 amino acids of the predicted extracellular domain (nucleotide 866 – 1459; GST-EC12; 55 kD fusion) and a portion of the intracellular domain (nucleotide 3230 – 4065; GST-cyto; 57 kD fusion). These regions were amplified using primers at the limits of these sequences on either cDNA clones or cDNA generated from Jurkat or Human Peripheral Blood RNA. Amplified DNA sequences were digested with restriction enzymes for cloning in-frame into GST expression vectors. Fusion proteins were expressed by IPTG induction in DH5 α and purified according to instructions from Pharmacia using glutathione-Sepharose

(Pharmacia). SDS-PAGE gel stained with Coomassie Blue showing induced and uninduced expression of the GST-CLASP-2-cyto construct is shown in FIG. 8. These recombinant proteins were expressed in DH5 α and purified according to instructions from Pharmacia using glutathione-Sepharose. Such recombinant proteins were used to generate antibodies (Josman laboratories) using a AVC Rapid Immunization Protocol.

The full length CLASP can easily be expressed from either the beginning of the hCLASP-2 sequence (in frame with nucleotide 2) or from the first or second methionine (nucleotide 278 or nucleotide 476, underlined in FIG. 1) through to the stop codon (nucleotide 4058). Assuming that the GST moiety has a weight of 26 kD, the total predicted sizes are 180, 168, and 164.5 kD respectively. Alternatively, other bacterial expression systems such as 6CLASP HIS tags, Calmodulin binding protein, maltose binding protein can also be used in a similar manner.

EXAMPLE 6

Expression of Recombinant CLASP-2A Polypeptide in Mammalian Cells

15 Example 6A. Secreted fusions

Several portions of the predicted extracellular domain were constructed as hIgG fusions using the CD5gamma-1 expression vector (kindly provided by B. Seed, Harvard University). Polypeptides were cloned into this vector in frame with a CD5 leader sequence that directs the fusion protein into the secretory pathway and in frame with a C-terminal hIgG(Fc) protein. This fusion can be secreted from cell lines such as 293 (Hsieh, J-C., 1999, Nature 398: 431-436). Sense primers with hCLASP-2 sequences beginning at nucleotide 866 and antisense primers at nucleotide 1459 (EC12-IgG), nucleotide 2389 (ECC-IgG) and nucleotide 2857 (ECM-IgG) were used to amplify portions of the extracellular domain for insertion into this vector. Recombinant vectors were purified by Maxiprep (Qiagen) and transfected into 293 EBNA- T cells (kindly provided by B. Seed, Harvard University) by calcium phosphate techniques (Sambrook and Maniatis). After 2-7 days, secreted expression was analyzed by an ELISA against the hIgG fusion using a goat F(ab')₂ anti human IgG(Fc) antibody (Jackson Immunolabs) and Protein-A-HRP (Pierce). Intracellular expression was monitored by immunofluorescence microscopy with a FITC labeled goat anti Human IgG(Fc) antibody (Caltag).

Example 6B. Intracellular fusions

Similar methods have been used to construct fusions for expression of full length hCLASP-2 isoforms as well as truncated C-terminal forms in other cell lines such as Jurkat. Recombinant hCLASP-2 fragments were either isolated by digestion of cDNA clones
5 or amplified by primers flanking specific regions (Please provide some specific regions). These can be cloned into expression vectors such as pBJ1-neo (Mark Davis, Stanford University), Peak12 (B. Seed, Harvard University), and pDsRed1-N1 (Clontech). pBJ1-neo and Peak12 allow untagged expression of recombinant proteins and pDsRed1-N1 will allow either untagged or a C-terminal Red fluorescent protein tag. These can be used to generate
10 protein or for expression of various forms for functional analyses.

EXAMPLE 7

Antisense Inhibition of CLASP-2 Expression

Example 7A. Inhibition of CLASP-2 expression *in vitro*

In this example, inhibition of CLASP-2 expression is examined using an *in vitro*
15 *cell-free* expression system. To identify the useful antisense oligonucleotides, a series of antisense phosphorothioate oligonucleotides (PS-ODNs), which span portion CLASP-2 sequence, can be systematically assayed for the ability to block CLASP-2 expression *in vitro*.

For inhibition of CLASP-2 expression *in vitro*, a CLASP-2 transcription/expression plasmid can be used according to standard methodology for *in vitro*
20 transcription and translation of sense CLASP-2 RNA. Coupled transcription-translation reactions can be performed with a reticulocyte lysate system (Promega TNTTM) according to standard conditions. Each coupled transcription/translation reaction can include CLASP-2 RNA transcribed from the expression plasmid, and a test antisense polynucleotide at a range of standard test concentrations, as well as the luciferase transcription/translation internal
25 control to normalize each reaction (see, *e.g.*, Sambrook *et al.*, *supra*, Ausubel *et al.*, *supra*). The translation reaction can also be performed with sense CLASP-2 RNA that is synthesized *in vitro* in a separate reaction and then added to the translation reaction. ³⁵S-Met is included in the reaction to label the translation products. The negative control is performed without added PS-ODN or a sense PS-ODN.

30 The labeled translation products can be separated by gel electrophoresis and quantitated after exposing the gel to a phosphorimager screen. The amount of CLASP-2 protein expressed in the presence of CLASP-2 specific PS-ODNs can be normalized to the co-expressed luciferase control.

Example 7B. Inhibition of CLASP-2 expression *ex vivo*

A. Reagents

Cells: Jurkat, Clone E6-1 ATCC TIB-152; 9D10 ATCC CRL8752; additional cells from the ATCC or NCI.

5 Media and solutions: RPMI 1640 medium, BioWhitaker; DMEM/M199 medium, BioWhitaker; EMEM, BioWhitaker; Fetal Bovine Serum, Summit (stored frozen at -20°C, stored thawed at 4°C); Trypsin-EDTA, GIBCO (catalogue #25300-054) (stored frozen at -20°C, stored thawed 4°C; Isoton II (stored at RT); DMSO (stored at RT); oligonucleotides (see Table 1 and FIG. 3, stored in solution at -20°C); PBS (Ca²⁺/Mg²⁺ free); TE; 10 mM Tris-HCL, pH 8.0; 1 mM EDTA.

To prepare oligonucleotide stocks: Oligonucleotide nucleotides (PS-ODNs) can dissolved in the appropriate amount of TE to make a concentrated stock solution (1 - 20 mM).

B. Treatment of cells *ex vivo* with antisense CLASP-2 oligonucleotides

15 Stock cultures of cells in log-phase growth (in T75 flask) can be used. Jurkat, and 9D10 cells are used in this assay. Jurkat and 9D10 are suspension cultures and are passed through dilutions in media. Cell density is measured using a Coulter counter or hemacytometer.

20 For 6-well dishes, 1.1×10^5 cells total per well, 2 ml/well is added. The amount of cells can be scaled up or down proportionally for 12-well, 100 mm, or 150 mm dishes. For example, for 12-well dishes, use 4.6×10^4 cells in 2 ml media; for 100 mm dishes use 6×10^5 cells in 10 ml media; for 150 mm dishes use 1.7×10^6 cells in 35 ml media.

25 An appropriate number of cells (as described in step 2 above) are collected, centrifuged and resuspended in media containing a range of ODN concentrations. The cells are treated in single, duplicate, or triplicate wells. Control wells are treated with TE or sense ODNs diluted in media.

The suspension cultures are washed and resuspended daily with PS-ODN media.

30 Suspension cultures are grown for 2-4 days. Cells are washed with PBS and density measured using a Coulter counter or a hemocytometer. If necessary, the cells are replated at 1.1×10^5 cells per well, 2 ml media per well, and fed with PS-ODN as described above.

Samples of the cells can also be harvested for analysis to determine the effects of CLASP-2 antisense ODNs. Samples are harvested for RNA and analyzed by either Northern analysis or RT-PCR for the presence of CLASP-2 mRNA. Functional consequences of CLASP-2 antisense ODNs can be analyzed by measuring the ability of Jurkat and 9D10 cells to be activated. Jurkat cells are activated by exposure to anti-CD3 and anti-CD28 crosslinking antibodies, and 9D10 cells are activated by exposure to anti-IgM crosslinking antibody or *P. aeruginosa* lipopolysaccharide. A hallmark of activation, calcium influx, can be measured by flow cytometry. Additionally, ELISA assays can be used to measure Interleukin-2 production from Jurkat cells and secreted IgM can be measured using standard assays from 9D10.

Table 5 below shows exemplary oligonucleotides for this assay:

Table 5

Oligo	Sequence 5'-3'	length	notes/comments
1	GAAGGCGATCATCACGT GGCCTTCCATCGC	30-mer	encompasses nucleotides 473-502 and spans the putative initiator methionine (underlined). The function of HC2A, 2B, 2C, and 2E isoforms can be eliminated by this oligonucleotide.
2	GCTTCAAGTAATGACTGG TGCAGAACATCTG	31-mer	Oligonucleotide that should recognize HC2A, 2B, 2D, 2E, and 2F. Encompasses nucleotides 2121-2151. Can be eliminate function of these CLASP-2 isoforms.
3	GCTCCTCCTCAGGCAGGC GCTATGGCTGTGG	34-mer	oligonucleotide specific for HC2C based upon a specific exon found at nucleotide 2927. Can eliminate only HC2D function.
4	GTAGGCCCGGTGCAGCGT GTCATACAGATGG	31-mer	oligonucleotide specific for HC2B, 2C, 2D and 2E based upon specific exon sequence found at nucleotide 3153. Can eliminate function of these CLASP-2 isoforms.
5	GCAATGTCTGAGACTTTC GATCATGAACATG	32-mer	oligonucleotide specific for HC2A, 2B, 2E, and 2F. Encompasses nucleotides 1987-2018. Can eliminate function of these CLASP-2 isoforms.
6	CAGGAGCTGGTTCTTAAA	18-mer	oligonucleotide specific for HC2A, 2D and 2E. Encompasses nucleotides 2219-2224. Can eliminate function of these CLASP-2 isoforms

Table 5 legend. All nucleotide numeration are relative to Human CLASP-2A (HC2A). See FIG. 2A.

EXAMPLE 8

Example 8A. Synthesis of carboxyl-termini PDZ-ligand peptides

The GST-PDZ fusion proteins are made following standard procedures. An exemplary GST-PDZ fusion protein was constructed as follows: A 572 bp fragment encoding two PDZ domains of the human neDLG gene (Genbank Accession No. U49089.1) was

amplified from total Jurkat RNA by RT-PCR according to standard protocols (Sambrook, Fritsch, and Maniatis, 1989, Molecular Cloning – A Laboratory Manual. Cold Spring Harbor Press.) using primers flanked by restriction endonuclease sites for cloning. Fragments were purified by Sephaglas (Pharmacia), digested with the appropriate enzymes, and ligated into the GST expression vector pGEX-3X (Pharmacia) cut with similar enzymes. Recombinant constructs were confirmed by sequencing. Fusion proteins were expressed by IPTG induction in DH5 α and purified using glutathione-Sepharose (Pharmacia) according to instructions from Pharmacia. Excess glutathione was removed using a PD10 desalting column (Pharmacia) and samples were diaconcentrated by placing the protein in dialysis tubing (14,000 MW cutoff) and laying the tubing on polyethylene glycol (3350; Sigma) until volume had been reduced by approximately 50%. Glycerol was then added to 35% final concentration and samples were stored at –20°C. These recombinant proteins have been used to generate antibodies (Josman laboratories) by standard protocols and for biochemical studies describe herein.

Synthetic peptides corresponding to the carboxyl-terminus of a protein of interest are synthesized by standard resin-based chemistry (*e.g.*, Fmoc), labeled with biotin at the amino-terminus when indicated, and cleaved from the resin using a halide containing acid (*e.g.*, trifluoroacetic acid). The synthetic peptides are then purified by reverse phase high performance liquid chromatography (HPLC) and the identity of the peptides are confirmed by mass spectrometry.

Example 8B. Measurement of CLASP-2 peptide binding to PDZ Domain-containing proteins

The binding of a biotinylated carboxyl-terminal peptide to a GST-PDZ fusion protein is measured as follows:

- (1) GST fusion protein containing one or more PDZ domain(s) is coated onto a protein-binding surface. The protein-binding surface is the surface of a polystyrene plate, which in some cases has been pre-treated by coating with 5 μ g/ml of goat-anti-GST polyclonal antibody followed by blocking with excess bovine serum albumin (BSA). The concentration of GST fusion protein used is 5–10 μ g/ml and the reaction of the GST fusion protein with the plate is carried out in PBS for 1 – 16 hours at 4°C. If not already blocked, the plate is then blocked with BSA (2% in PBS, 2 hours, 4°C)
- (2) The plate is washed with PBS.

- (3) The biotinylated peptide (generally 0.2–20 μ M) is then added to the plate and allowed to react in PBS/2% BSA buffer with the GST fusion protein for 10 minutes at 4°C followed by 20 minutes at 25°C. In cases where competition between a labeled (biotinylated) and unlabeled (non-biotinylated) peptide is performed, the unlabeled peptide is added immediately prior to adding the labeled peptide.
- (4) The plate is washed with PBS.
- (5) 0.5 μ g/ml streptavidin-HRP conjugate is added to the plate in PBS/2 % BSA buffer and allowed to react for 20 minutes at 4°C.
- (6) The plate is washed 5 X with detergent (tween 20) containing solution.
- (7) The plate is developed by addition of HRP-substrate solution for 20 minutes at room temperature.
- (8) The reaction of the HRP and its substrate is terminated by addition of 1 M sulfuric acid.
- (9) The optical density of each well of the plate is read at 450 nm.

In cases where measurement of the apparent affinity of PDZ-ligand interaction is desired, the above procedure is carried out with multiple concentrations of the labeled peptide being used in a single experiment. A plot of binding versus peptide concentration added is then fit to the equation:

$$\text{Binding [peptide]} = \text{Saturation Binding} \times ([\text{peptide}] / ([\text{peptide}] + K_d))$$

where “Binding [peptide]” is the binding of a given concentration of peptide to the GST-PDZ fusion protein minus binding to the GST alone control, “K_d” is the apparent affinity of the binding reaction, and “Saturation Binding” is computed to allow the best fit of the data to the above equation. The term apparent affinity is used because the reaction may not reach equilibrium during the duration of the binding reaction in which case the apparent affinity would underestimate the actual affinity (*i.e.*, actual K_d < observed K_d).

EXAMPLE 9

Expression of human CLASP -2 in activated T-cells

General experimental design

The expression profiles of human CLASP-2 in T cells upon T cell activation was determined by Northern analysis. Jurkat E6 lymphoblasts were activated by treatment with anti-CD28, PMA, and Ionomycin. Subsequently, total RNA was extracted from cell aliquots harvested at 0, 1, 2, 4, 8, and 14 hours post activation. The RNA concentration of each preparation was determined by the absorption at 260 nm using a spectrophotometer and concentrations of the different RNA preparations were adjusted such that equal quantities of each RNA preparation could be subjected to Northern analysis. Even gel loading was monitored by ethidium bromide staining of the formaldehyde-agarose gel. Northern membranes were hybridized to radioactively labeled probes corresponding to portions of human CLASP-2 and human beta-actin. Expression levels of CLASP-2 at different time points post T-cell activation are proportional to the radioactive signal generated by hybridization by the CLASP-2 specific radioactively labeled probe that remained bound to the Northern membrane under stringent washing conditions. The entire experiment was done in duplicate.

Jurkat E6 cell activation

Jurkat E6 cells were maintained and tested in complete IMDM medium supplemented with 2 mM glutamine, 10 mM HEPES, 100 u/mL penicillin, 100 µg/mL streptomycin, 0.1 mM nonessential amino acids, 1 mM sodium pyruvate (Gibco/BRL), 50 µM beta mercaptoethanol (Sigma), and 10% fetal calf serum (Gemini). T cells were activated as described per Fraser et al., using 0.1 µg/mL mouse anti-human CD28 monoclonal antibody (PharMingen International catalog number 33741A), 50 ng/mL PMA (Sigma), and 1 µM ionomycin (Calbiochem). Following incubation at 37°C and 5.0% v/v CO₂, 0.5 x 10⁶ cells were harvested by centrifugation at 500 x g for 10 minutes (min) at room temperature at 0, 1, 2, 4, 8 and 14 hours post activation and subjected to RNA extraction.

For RNA preparation, probe labelling and Northern analysis protocols, see methods and procedures described in Example 2 above. The CLASP-2 specific probe encompassing nucleotides 5352 to 5922 was generated by PCR from a plasmid containing cloned CLASP-2 cDNA sequences using primers C2S12 and C2AS21.

Hybridization, Washing, and Exposure

Blots were washed twice in 2x SSC 0.1% SDS for 10 min each at 60° C and then twice in 0.2x SSC 0.1% SDS for 10 min each at 60° C, followed by a 5' wash in 2xSSC at 60° C. Exposure to KODAK BIOMAX MS film was carried out at minus 80° C using

amplifying screens. Typically, exposure times were 10 to 36 hours. Signal intensities on Northern membranes were quantified by the use of a phosphor imager system (STORM, Molecular Dynamics). Signals were counted in the “volume report” mode.

Results

- 5 CLASP-2 expression levels as determined by Northern analysis (FIG. 14) slightly decrease at 1 hour post activation. The maximum decrease of approximately 36 % is seen at 2 hours post activation. Expression levels augment again at 4 hours post activation but do not attain the level that is seen before activation (0 hours). Intensities of CLASP-2-specific signals on the Northern blot were quantified by phosphor imager analysis.
- 10 Rectangles were drawn around the areas of CLASP-2-specific signal and total quantity of signal was determined by the “volume report” mode; phosphor imager quantification results of two entirely independent experiments are shown in the diagram (green bars corresponds to Northern blot shown). The above result suggests, that transcriptional control of CLASP-2 expression and T-cell activation are functionally linked to each other.

EXAMPLE 10

- Chromosomal location of CLASP-2 and possible disease associations
- CLASP-2 cDNA sequences have been mapped to the genomic clone (GI:9926440, GI:9988160) by use of sequence homology bioinformatics tools BLAST.
- Clone (GI:9926440, GI:9988160) has previously been mapped to the
- 20 chromosomal location 13q12-q13. The literature research reports that the mutations, deletions, rearrangements, disomies and/or breakpoints (in general: chromosomal aberrations) in below listed genes make the genes strong candidates for the onset of the listed diseases/disorders. Because the CLASP-2 gene is localized in the chromosome location 13q12-q13, abnormal CLASP-2 gene regulation or deletion, rearrangement and/or mutations
- 25 in CLASP-2 locus might be directly or indirectly associated with the onset of the listed diseases. Further, CLASP-2 gene can be used as a genetic probe to detect the abnormality in regions of these below listed genes and as a diagnostic marker for the related disease/disorders.

CANDIDATE GENES	LOCUS	RELATED DISEASE/DISORDERS
<u>IPF1:Insulin promoter factor1</u>	13q12.1	MODY4: non insulin-dependent juvenile type, Defect in pancreatic islet development and insulin transcription.
BRCA2	13q12.3	BCLL2: B cell lymphoma, deletion encompassing BRCA2 causes B cell lymphoma. BRCA2 is one of the responsible genes for DNA repairing in S phase.
	13q13.1-q14.3	Deletion of these locus causes MDS6: Myelo dysplastic syndrome type 6 including AML.

The present invention is not to be limited in scope by the exemplified
embodiments which are intended as illustrations of single aspects of the invention, and any
5 clones, DNA or amino acid sequences which are functionally equivalent are within the scope
of the invention. Indeed, various modifications of the invention in addition to those described
herein will become apparent to those skilled in the art from the foregoing description and
accompanying drawings. Such modifications are intended to fall within the scope of the
appended claims. It is also to be understood that all base pair sizes given for nucleotides are
10 approximate and are used for purposes of description.

All publications and patent documents cited above are hereby incorporated by
reference in their entirety for all purposes to the same extent as if each were so individually
denoted. Without wishing to exclude incorporating the remainder of the following patent
applications, the following sections of the following patent applications are explicitly
